Rhizobium etli CFN42 bacteroids from bean nodules possessed an abundant 16-kDa protein (BacS) that was found in the membrane pellet after cell disruption. This protein was not detected in bacteria cultured in tryptone-yeast extract. In minimal media, it was produced at low oxygen concentration but not in a mutant whose nifA was disrupted. N-terminal sequencing of the protein led to isolation of a bacS DNA fragment. DNA hybridization and nucleotide sequencing revealed three copies of the bacS gene, all residing on the main symbiotic plasmid of strain CFN42. A stretch of 304 nucleotides, exactly conserved upstream of all three bacS open reading frames, had very close matches with the NifA and sigma 54 consensus binding sequences. The only bacS homology in the genetic sequence databases was to three hypothetical proteins of unknown function, all from rhizobial species. Mutation and genetic complementation indicated that each of the bacS genes gives rise to a BacS polypeptide. Mutants disrupted or deleted in all three genes did not produce the BacS polypeptide but were Nod+ and Fix+. On Phaseolus vulgaris.

Many leguminous plants obtain nitrogen via symbiosis in root and stem nodules with bacteria known as rhizobia, belonging to several branches of the α and β subdivisions of the Proteobacteria (Moulin et al. 2001). In infected nodule cells, the bacteria are present as bacteroids, whose composition and structure differ from those of free-living bacteria (Franssen et al. 1992; Planque et al. 1979). Bacteroids fix nitrogen that is then assimilated by the host. The nif and fix genes involved in nitrogen fixation are induced as part of the conversion of the bacteria into bacteroids. The NifA protein activates the expression of nifHDK, fixABCX, and nifN (genes for nitrogenase, electron transport to nitrogenase, and ferredoxin, respectively) in response to low oxygen concentration (Fischer 1994; Mick 1992).

In Rhizobium etli CFN42, one of six plasmids carries most of the genes required to form nodules and fix nitrogen on bean roots (Brom et al. 1992; Cevallos et al. 1989; Palacios et al. 1985). This symbiotic (Sym) plasmid is 390 kb in length, with 10 families of internally reiterated DNA sequences of two to three elements each (Girard et al. 1991). In addition to well-established nod, nif, and fix genes, this and other symbiotic plasmids carry other genes that are expressed during symbiosis but whose functions are unknown (Girard et al. 1996; Perret et al. 1999).

Work initiated to study bacteroid membrane proteins revealed an abundant bacteroid protein of R. etli CFN42, designated BacS. Its synthesis ex planta was dependent on microaerobic conditions and nifA. Three similar open reading frames (ORFs) on the Sym plasmid encoded BacS polypeptides. The possible role of this protein in symbiosis was tested by isolation of mutants in which all copies of bacS were deleted or disrupted.

RESULTS

Abundant bacteroid protein lacking in aerobic cultures.
Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) revealed an abundant, approximately 16-kDa protein in bacteroids of R. etli strain CE3 (Fig. 1). It was designated BacS (bacteroid protein of 16 kDa). This protein was not detected from aerobically grown CE3 bacteria by either Coomassie staining or immunoblot analysis, even when lanes were overloaded with the contents of aerobically grown cells (Fig. 1, lanes 5 and 6). After rupture of bacteroids by sonication, BacS was found in the cell fraction that pelletted after centrifugation at 15,000 × g for 60 min (Fig. 2). The protein was not released from the pelletted fraction with 2 M sodium chloride or 1 M magnesium chloride (not shown).

Induction ex planta at low O2 concentration, requiring nifA.
As noted above, strain CE3 grown under ambient atmospheric gas composition did not express detectable levels of BacS. However, strain CE3 grown with 1% O2 (5% ambient air, 95% purified nitrogen) or no O2 in the gas space above minimal liquid medium did express the protein, as evidenced by a band detected with antiserum against BacS migrating at the appropriate rate on SDS-PAGE (Fig. 3, lanes 4 to 7). Growth in nodule extract (Noel et al. 1988), root extract (Duelli 1999), limiting FeCl3, or in medium buffered at pH 5 or 7 did not result in detectable levels of the protein unless the cultures were also grown microaerobically (not shown). These additional conditions did not significantly affect the microaerobically induced level of expression, nor did substituting glucose for succinate as the major carbon source (not shown). CE3 grown microaerobically in tryptone-yeast (TY) extract rather than in minimal media did not induce detectable levels of the protein (not shown). Addition of nitrate to cultures also allowed expression of BacS under conditions of low oxygen concentration. The nitrate stimulated growth of CE3 when no oxygen was added to the headspace of the stopped vessels after the nitrogen purge but led to apparently lower production...
of BacS relative to total proteins (Fig. 3, lanes 4 to 7). The level of expression of the protein ex planta was always much lower than in the bacteroids (Fig. 3, lane 8).

The nifA gene was required for production of BacS under these conditions. Under conditions that elicited synthesis of the protein in strain CE3 (Fig. 4, lane 1), strain CFNX247 (nifA, Table 1) did not exhibit detectable levels (Fig. 4, lane 2).

Cloning of the 5' portion of bacS and its use to reveal multiple bacS genes on pSym.

Twenty-nine amino acid (aa) residues were identified by N-terminal sequencing of BacS excised from an SDS-PAGE blot: T, K, I, S, E, R, S, F, E, T, I, E, N, P, G, S, X, D, L, K, V, P, D, Q, F, G, A, S, and R. The purity of the protein was such that, in each of the first five cycles of sequencing, the highest contaminating amino acid was present at 20% or less of the one indicated above. By use of degenerate oligonucleotide primers based on this sequence, a polymerase chain reaction (PCR) product whose DNA sequence matched the N-terminal protein sequence was cloned (plasmid pOJ1, Table 1).

CE3 genomic DNA digested with BamHI, EcoRI, EcoRV, and PstI was analyzed by Southern hybridization using pOJ1 as probe (Fig. 5). With one exception, restriction digests with one or two of these enzymes resulted in two or three fragments hybridizing with the probe. Only the BamHI and EcoRI double digest gave a single hybridizing band (not shown). None of the restriction enzymes cut within the DNA sequence of the hybridization probe; therefore, the multiple hybridization bands indicated potentially three copies of the gene, with the BamHI and EcoRI restriction sites conserved in all three genetic locations.

A strain cured of the pSym (CFNX89) did not produce BacS under inducing conditions ex planta (Fig. 4, lane 4) and lacked all of the above-described bacS-hybridizing restriction fragments (data not shown). The nucleotide sequence of the N-terminal region of BacS was compared with data obtained from total nucleotide sequencing of the CE3 symbiotic plasmid (V. González, P. Bustos, M. Á. Ramírez-Romero, A. Medrano-Soto, H. Salgado, I. Hernández-González, J. C. Hernández-Celis, V. Quintero, G. Moreno-Hagelsieb, L. Girard, O. Rodríguez, M. Flores, M. A. Cevallos, J. Collado-Vides, D. Romero, and G. Dávila, unpublished data). The comparison indicated high homology with three BamHI fragments of the pSym (B03, B27, and B80 according to the nomenclature of Girard et al. 1991). The published sizes of these BamHI fragments (Girard et al. 1991) matched the results of Southern hybridization with pOJ1 described above. Independently of the symbiotic plasmid genome sequencing project, cloned DNA fragments that included two bacS ORFs were sequenced.

The bacS ORFs in pSym BamHI fragments B03, B27, and B80.

The nucleotide sequences of the three bacS ORFs and 382 nucleotides (nt) upstream are shown in Figure 6. The three sequences are very highly conserved (Fig. 6), but diverge immediately upstream and downstream of the sequence shown. All three DNA sequences have the same potential NifA upstream activator sequences and a consensus $\sigma^70$ promoter sequence (Fig. 6). The ORFs determined within the B03, B27, and B80 DNA (bacS$_{032780}$) would result in a 151-aa protein (Fig. 6) with

![Fig. 1. BacS is an abundant 16-kDa bacteroid protein. Wild-type CE3 bacteroids or bacteria grown ex planta in rich medium (TY) or minimal medium (YGM) in ambient atmosphere were extracted with sodium dodecyl sulfate (SDS) and analyzed by SDS-polyacrylamide gel electrophoresis. A, Gels were stained with Coomassie blue. B, Immunoblots of identically loaded lanes were reacted with polyclonal antibodies to BacS. A and B, Molecular weight markers (lane 1), bacteroids (lane 2), bacteria grown in TY medium (lanes 3 and 5), or grown in YGM buffered at pH 7 (lanes 4 and 6). Lanes 5 and 6 were overloaded to emphasize the lack of immunologically detectable expression of BacS. The arrows indicate the location of BacS as determined by immunoblots of gels in which BacS was better resolved from the abundant protein migrating just above it (data not shown).](image1)

![Fig. 2. BacS associates with the insoluble fraction of bacteroids. Envelope (lane 2) and soluble (lane 1) cell fractions of CE3 bacteroids (prepared as described in Methods) were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. A, Gel stained with Coomassie blue. B, Western blot of the lower portion of a gel run identically to that of A and reacted with polyclonal antisera to BacS. The arrows indicate the position of BacS.](image2)
a molecular mass of 16.6 kDa. There were no obvious subcellular targeting sequences for the protein upstream of the N terminus of the mature protein. Computer analysis (Brendel et al. 1992) also did not reveal appropriate sequences long enough to span the entire length of either membrane lipid bilayer.

A search of the data bases showed significant homology with hypothetical proteins of unknown function (Fig. 7) encoded by three ORFs: Y4wP from the symbiotic plasmid of *Sinorhizobium fredii* NGR234 (Freiberg et al. 1997), Np107027.1 from *Mesorhizobium loti* (Kaneko et al. 2000), and SMc00777 AA from *S. meliloti* (Galibert et al. 2001). The hypothetical protein encoded by the y4wP ORF has a length of 135 aa residues and an estimated molecular mass of 14.9 kDa. The Y4wP protein had 50 identical residues and 87 similar residues with BacS (Fig. 7). The hypothetical protein from *M. loti* has 152 aa residues, similar to the 151 residues in BacS. The homology spans almost the entire length of both proteins with 47% identity and 67% similarity (Fig. 7). The hypothetical protein from *S. meliloti* has 148 aa residues. The homology spans residues 3 to 146 of SMc00777AA, with 35% identity and 53% similarity (Fig. 7). The predicted amino acid sequences of BacS and these three homologs are aligned in Figure 7.

In some experiments, the BacS polyclonal antibodies appeared to react weakly with *Phaseolus vulgaris* leghemoglobin on Western blots of the soluble nodule plant proteins (data not shown). Prompted by this observation, leghemoglobin amino acid sequences were compared with the sequences of BacS and its homologs in the other rhizobial species (Fig. 7). Interestingly, without gapping, there was a conservation in the spacing of five (PvLb) or six (PsLb) of the first seven residues that are conserved in all the rhizobial BacS homologs (Fig. 7). One of these conserved residues was a histidine (residue 87 in BacS) (Fig. 7) which, in leghemoglobin, is one of two conserved histidines crucial in coordinating the iron of the heme and directing its binding to oxygen. At the position of the other leghemoglobin histidine, BacS also has a histidine (residue 118 in BacS) (Fig. 7). At this position, the three BacS homologs have a glutamine.

**Phenotypes of BacS− mutants.**

*R. etli* CFNX250 (D. Romero, A. Corvera, A. Geniaux, S. Brom, E. Valencia-Morales, C. Rodriguez, and B. Valderrama, unpublished) is Nod+Fix+ but has a pSym deletion (resulting in pGM1, Table 1) that eliminates two-thirds of the pSym of strains CFN42 and CE3, including two of the bacS ORFs. The remaining ORF (in BamHI fragment B03) allows the production of BacS in normal amounts (Fig. 8, lane 1). This copy of bacS was mutated in strain CFNX250 by insertion of DNA that confers tetracycline resistance to generate bacS− isolates. These isolates did not produce detectable levels of BacS ex

![Fig. 3. BacS is produced ex planta under microaerobic conditions.](image)

Wild-type CE3 grown under aerobic, 1% O2, or anaerobic conditions with or without nitrate was analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. A, Gel stained with Coomassie blue. B, Immunoblot of identically loaded lanes was reacted with polyclonal antibodies to BacS. A and B, Bacteria were grown in YGM medium (buffered at pH 7) with nitrate (lanes 2, 4, and 6) or without nitrate (lanes 3, 5, and 7). The gas above the liquid phases of the cultures was ambient air (lanes 2 and 3), nitrogen supplemented with 5% air (lanes 4 and 5), or only nitrogen (lanes 6 and 7). Arrows indicate the position of BacS. Lane 1, molecular weight markers; lane 8, samples of a bacteroid extract.

![Fig. 4. nifA and pSym are required for production of BacS.](image)

Strains CE3 (wild type), CFNX247 (nifA−), and CFNX89 (pSym−) were grown under 1% oxygen conditions and analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. A, Portions of two gels stained with Coomassie blue. B, Portions of immunoblots of lanes that had been loaded identically to those in A were reacted with polyclonal antibodies to BacS. A and B, CE3 (lane 1), CFNX247 (lane 2), or CFNX89 (lane 4) cells were grown at 1% O2 in YSM buffered at pH 7. CE3 bacteroids were processed for lane 3. An arrow indicates the position of BacS.
plasmid pOJB80F) were transferred into these mutants, the transconjugant strains produced BacS ex planta under inducing conditions (not shown). These complementation results indicated that all three of the bacS genes can be expressed under these conditions.

**DISCUSSION**

BacS was highly expressed in CE3 bacteroids but was not detectably expressed in the free-living form unless the bacteria were cultivated under microaerobic conditions. Production of BacS ex planta under low oxygen does not occur in a nifA mutant strain. Upstream of all three reiterated bacS genes, three matches with the consensus upstream activator sequence (UAS) for NifA (Ditta 1989) are present (Fig 6, underlined sequences beginning at nucleotides 9, 43, and 72). A sequence that corresponds with the consensus σ54-dependent promoter occurs approximately 100 nt downstream of the last UAS (Fig 6, nucleotide 183). Although these observations provide strong evidence of regulation via NifA and microaerobic conditions in minimal media, no expression was detected in microaerobic TY cultures and the level of expression in bacteroids was much higher than in bacteria under any condition tested ex planta. Therefore, there must be conditions in addition to microaerobiosis that affect the expression of this protein. There may be another regulator in addition to NifA, or NifA activity may be limited under the ex planta conditions tested.

The BacS protein was found among the nonsoluble proteins when centrifuged at 15,000 to 150,000 × g. After sonication, much of it appears to be lost with the broken cell debris. However, its structure does not have features consistent with integral inner or outer membrane proteins and, in some experiments, it was found also in the soluble fraction. BacS from bacteroids is stained by silver after periodate treatment, which may indicate that it is a glycoprotein. However, it does not migrate at a higher molecular weight in SDS-PAGE than expected, as is common for most glycoproteins.

The three ORFs for bacS are located in and near the nod and nif region of pSym. Also, all three are located within the type IV amplicon, one of the defined regions of DNA that is prone to the formation of frequent tandem amplification (Romero et al. 1995). All the known amplicons in R. etli are concentrated within the region of pSym in which most of the symbiotic genes are located (Romero et al. 1995). Further, a 135-kb region sufficient to reestablish nodulation and nitrogen fixation in otherwise pSym - R. etli (D. Romero, unpublished) contains one of the bacS genes.

Homologs to bacS are present in all rhizobial genomes sequenced thus far. The bacS homolog ORF, y4wP, in S. fredii NGR223 is directly upstream of nifRD, downstream of nifS and nifW, and has a putative NifA-dependent upstream activator and a putative σ54-dependent promoter. In M. loti, the homologous ORF is just outside the symbiosis island on the chromosome. Therefore, in both of these species, as in R. etli, the bacS homolog is found near symbiotically significant genes. In both M. loti and S. meliloti, a His-GTG-tRNA occurs directly downstream of the ORFs. As more sequence data becomes available, the relative location of the bacS genes may provide more clues to the BacS function.

One possible clue to the function of BacS is that its sequence aligns in a certain way with leghemoglobins (Fig. 7). Conservation of the primary structure in globins across phylogeny is low (Moens et al. 1996). The sequences from diverse organisms can be aligned only by the relative positioning of very few residues, particularly the two conserved histidine–glutamine residues. Computer analysis of the secondary structure of BacS indicates that these two residues are located in two different helices which could correspond to the two helices where the histidine–glutamine residues from the leghemoglobin model are located. Conservation and alignment of the first six of seven identical residues between the BacS rhizobial homologs and leghemoglobin, including the exact alignment of the histidine–glutamine residues that are crucial in hemoglobin function, along with the possible similarities in secondary structure, indicate that BacS may be related to hemoglobins.

In a paper by Perret and associates (1999), y4wP transcription was not detected under conditions of induction with daidzein or in bacteroids from Vigna unguiculata determinate and Cajanus cajan indeterminate nodules. However, they did not test bacteroids from bean nodules or bacteria grown ex planta under conditions of low oxygen, the conditions in which expression of bacS was detected in R. etli.

*nifA*-dependent expression ex planta, the location of the three bacS ORFs in and near the nod and nif region on pSym, and the bacteroids’ high level of bacS expression all suggest an importance of this protein to R. etli during symbiosis. Therefore, the lack of an Nif or Fix phenotype in BacS mutants is surprising. It may be that absence of BacS can be compensated for by another protein, similar to the complementing proteins NodO and NodE in R. leguminosarum bv. viciae, in which either protein is sufficient to promote normal infection thread growth despite having disparate biochemical activities (Walker and Downie 2000). Alternatively, BacS may be required under a set of conditions or a different host not yet tested.

![Fig. 5. CE3 genomic DNA contains multiple copies of bacS. CE3 genomic DNA was digested with restriction enzymes BamHI (lane 1), EcoRI (lane 2), EcoRV (lane 3), and PsrI (lane 4). After electrophoresis, DNA fragments were blotted and probed with the 32P-labeled pOJ1. The migration of standard DNA is indicated by the positions labeled at the left of the blot.](image-url)
MATERIALS AND METHODS

Bacterial strains and growth media.

*R. etli* strains ultimately were derived from bean nodule isolate *R. etli* CFN42 (Quinto et al. 1982), with strain CE3 (Table 1) being the wild-type control. Liquid cultures were grown at 30°C in TY extract + CaCl₂ (Noel et al. 1984), minimal medium YGM (Tao et al. 1992), or minimal medium YSM which was identical to YGM except that 0.4% succinate was substituted for the glucose. Solidified medium contained 1.5% Bacto...
agar. Antibiotics were added in the following concentrations: gentamicin at 30 µg/ml, kanamycin at 30 µg/ml, nalidixic acid at 20 µg/ml, spectinomycin at 100 µg/ml, streptomycin at 200 µg/ml, and tetracycline at 5 or 1 µg/ml.

Escherichia coli strains were grown at 37°C in Luria-Bertani (LB) medium (Sambrook et al. 1989) in liquid shake cultures or on 1.5% Bacto agar. Antibiotics were added in the following concentrations: 30 µg of gentamicin per ml, 100 µg of spectinomycin per ml, and 15 µg of tetracycline per ml.

**Plant tests.**

*P. vulgaris* cv. Midnight (bean) seeds were surface sterilized with commercial bleach, germinated for 2 days, and transferred to growth pouches (Mega International, Minneapolis, MN) containing nitrogen-free RBN plant medium (Noel et al. 1984; Wacek and Brill 1976). The seedlings were inoculated with bacteria grown in TY broth, and Fix activity was determined by acetylene reduction of intact roots in stopped serum vials (Noel et al. 1982, 1984).

### Protein analysis by SDS PAGE.

Bacterial cells and isolated bacteroids were prepared in SDS buffer. The extracts were separated by SDS-PAGE (Laemmli 1970) with 12 or 15% acrylamide in the separating gel. The gel was stained with Coomassie blue (Dzanud et al. 1984) or electroblotted onto nitrocellulose. The blot was incubated with rabbit polyclonal antiserum as described by Carlson and associates (1987). Bound antibodies were detected with goat alkaline-phosphatase-conjugated anti-rabbit immunoglobulin G (Sigma-Aldrich, St. Louis) that was developed with 5-bromo-4-chloro-3-indolyl phosphate (Blake et al. 1984). Molecular weight markers (RP756 from Amersham) included myosin, 200 kb; phosphorylase b, 92.5 kb; bovine serum albumin, 69 kb; ovalbumin, 46 kb; carbonic anhydrase, 30 kb; trypsin inhibitor, 21.5 kb; and lysozyme, 14.3 kb.

### Antibody production.

Subcutaneous injections into New Zealand white rabbits were administered using a total of 0.4 to 0.5 cc of a suspension of

**Fig. 7.** Alignment of the amino acid sequences of BacS, Y4wP, MLhp, and leghemoglobin from *Phaseolus vulgaris* and *Pisum sativum*. The sequences are aligned first to compare BacS and the three rhizobial hypothetical proteins (Y4wP, MLhp, and SMhp). Identical residues between BacS03 and these hypothetical rhizobial proteins are in bold and similar residues are underlined. Residues that are identical for all four polypeptides are separated by spaces. Y4wP is from the symbiotic plasmid of *Sinorhizobium fredii* NGR234, MLhp (Np107027.1) from *Mesorhizobium loti*, and SMhp (SMc00777AA) from *Sinorhizobium meliloti*. Below these three BacS homologs, two leghemoglobin sequences are presented without any gapping, except for one which was necessary to maintain alignment between the leghemoglobins. The amino acid sequences for the leghemoglobin from *Phaseolus vulgaris* (PvLb) and *Pisum sativum* (PsLb) have residues in bold where they are identical at the same position with residues that are conserved in BacS and all three hypothetical rhizobial proteins. Asterisks indicate the positions of the well-known distal and proximal heme-coordinating histidines in the leghemoglobins.
BacS protein antigen, emulsified from the BacS portion of a nitrocellulose blot of an SDS-PAGE gel, in phosphate-buffered saline, pH 7.2 and Freund's adjuvant (Sigma-Aldrich) (Harlow and Lane 1988). Boosters were given intramuscularly or intravenously once every 2 weeks for a total of 4 to 8 weeks. To increase the monospecificity, acetone powders of CE3 cell cultures grown aerobically were added to the undiluted antisera at a 1% (wt/vol) concentration and incubated for 30 min at 4°C (Harlow & Lane. 1988). The resulting suspension was centrifuged at 10,000 × g for 10 min and the supernatant used as the source of antibodies.

**Isolation of bacteroids and separation into cell envelope and soluble portions.**

Bacteroids and the soluble nodule plant proteins were harvested from crushed nodules as described by Tao and associates (1992). Isolated bacteroids were resuspended in 50 mM Tris-HCl, sonicated on ice with nine 20-sec bursts, and centrifuged at 13,000 × g for 60 min. The resulting soluble and insoluble (cell envelope) fractions were analyzed by SDS PAGE and Western blot.

**Expression of the protein ex planta.**

Anaerobic and microaerobic cultures were grown in tubes sealed with serum stoppers, in which the headspace was purged of air with nitrogen after the inoculum was added. The supernatant was removed and centrifuged at 15,000 × g for 60 min. The resulting soluble and insoluble fractions were analyzed by SDS PAGE and Western blot.

**Southern analysis.**

Plasmid and genomic DNA were isolated by use of cetyltrimethylammonium bromide (Ausubel et al. 1994; Del Sal et al. 1989). DNA digested with restriction enzymes was fractionated by electrophoresis on 0.7% (wt/vol) agarose and electroblotted to Nytran-Plus membrane (Schleicher and Schuell). Prehybridization, hybridization, and washes were performed at 65°C. After prehybridization in buffer (containing 0.25 M Na2HPO4, pH 7.2, 5% SDS, and salmon sperm DNA at 10 μg/ml) overnight, the membrane was incubated with the denatured plasmid DNA (labeled with 32P-dATP by random priming [Pharmacia]) in fresh buffer for 5 h. The membrane then was rinsed twice in wash A (20 mM Na2HPO4, pH 7.2, and 5% SDS) and twice in wash B (20 mM Na2HPO4, pH 7.2, and 1% SDS) for 15 min each, sealed in plastic, and subjected to autoradiography.

**Cloning of the PCR product and a BamHI–EcoRI fragment overlapping a portion of bacS.**

Using *R. meliloti* codon preferences from J. M. Cherry *(personal communication)*, degenerate oligonucleotide sequences

* PCR = polymerase chain reaction.

* Strains and plasmids with a tetracycline resistance cassette (Tc) inserted in the *BamH*I restriction site of the bacS gene.
Fig. 8. Nod‘Fix’ mutant strain CE461 does not express bacS ex planta or in the nodule. 

A. Gels stained with Coomassie blue. B. Immunoblots of identically loaded lanes were reacted with polyclonal antibodies to BacS. 

ACKNOWLEDGMENTS

This work was supported by grants R15 GM57775-01 from NIH and DE-FG02-98ER20307 from DOE. We thank S. Brom, M. Cevallos, and L. Girard from Centro de Investigacion sobre Fijacion de Nitrogeno in Cuernavaca for helpful discussions, pBG27, and L. Mende-Mueller at the Medical College of Wisconsin for the N-terminal sequencing of BacS, and we acknowledge the use of the DNA Sequencing Facility at the University of Wisconsin-Milwaukee.
