Abstract

In this paper, we introduce a new three-parameter generalized version of the Gompertz model called the odd log-logistic Gompertz (OLLGo) distribution. It includes some well-known lifetime

distributions such as Gompertz (Go) and odd log-logistic exponential (OLLE) as special sub-models. This new distribution is quite flexible and can be used effectively in modeling survival data and reliability problems. It can have a decreasing, increasing and bathtub-shaped failure rate function depending on its parameters. Some mathematical properties of the new distribution, such as closed-form expressions for the density, cumulative distribution, hazard rate function, the k th order moment, moment generating function and the quantile measure are provided. We discuss maximum likelihood estimation of the OLLGo parameters as well as three other estimation methods from one observed sample. The flexibility and usefulness of the new distribution is illustrated by means of application to a real data set.

1. Introduction

The Gompertz distribution is a flexible distribution that can be skewed to the right or to the left. This distribution is a generalization of the exponential distribution and is commonly used in many applied problems, particularly in lifetime data analysis [23, page 25]. The Gompertz distribution is considered for the analysis of survival, in some areas such as gerontology [5], computer [28], biology [10] and marketing science [3]. The hazard rate function of this distribution is an increasing function and often employed to describe the distribution of adult human life spans by actuaries and demographers [32]. The Gompertz distribution with parameters $a > 0$ and $b > 0$ denoted by $Go(a, b)$, has the cumulative distribution function (cdf)

$$(1.1) G(x, a, b) = 1 - e^{-\frac{b}{a}} (e^{ax} - 1), x > 0, a > 0, b > 0,$$

and the probability density function (pdf)

$$(1.2) g(x, a, b) = be^{ax} e^{-\frac{b}{a}} (e^{ax} - 1), x > 0:$$

In this paper, we introduce a new generalization of Gompertz distribution which by product of the application of the Gompertz distribution to the odd log-logistic generator proposed by [15], called the OLLGo distribution. Several generalized distributions have been proposed via this methodology. The idea is similar to introducing some generalization of the well-known distributions such as: odd-log-logistic Weibull distribution [7] and odd log logistic exponential distribution (OLLE), [15]. The OLLGo distribution includes some well-known distributions and offers a more flexible distribution for modeling lifetime data in terms of its hazard rate functions that are decreasing, increasing, upside-down bathtub and bathtub shaped. Several mathematical properties of this new model are provided in order to attract wider applications in reliability, engineering and other areas of research.

The paper is organized as follows: In Section 2, we define cumulative distribution, probability density, and failure rate functions, and outline some special cases of the OLLGo distribution. In Section 3 we provide some extensions and properties of the cdf, pdf, r th moment and moment generating function (mgf) of the OLLGo distribution in the form of power series. Furthermore, in this section, we derive the corresponding expressions for the cdf and pdf of the order statistics and quantile measure from the proposed distribution. Section 4 deals with certain characterizations of OLLGo distribution. In Section 5, we discuss maximum likelihood estimation (MLE) of the OLLGo parameters from one observed sample. Section 6 contains Monte Carlo simulation results on the finite sample behavior of

MLEs as well as three other estimation methods. Finally, application of the OLLGo model using a real data set is considered in Section 7.

2. The OLLGo model

In this section, we introduce the three-parameter OLLGo distribution. The idea of this distribution rises from the following general class: If $G(\cdot)$ denotes the cdf of a random variable then a generalized class of distributions, called the Generalized log-logistic family, introduced by Gleaton and Lynch (2006) is

$$(2.1) F(x) = \frac{G(x; \xi)^\alpha}{G(x; \xi)^\alpha + \bar{G}(x; \xi)^\alpha}, x \in \mathbb{R}.$$

Let $g(x; \xi) = \frac{dG(x; \xi)}{dx}$ be the density of the baseline distribution. Then, the probability density function corresponding to (2.1) is

$$(2.2) f(x) = \frac{\alpha g(x; \xi) G(x; \xi)^{\alpha-1} \bar{G}(x; \xi)^{\alpha-1}}{[G(x; \xi)^\alpha + \bar{G}(x; \xi)^\alpha]^2}, x \in \mathbb{R}:$$

As stated in the paper by Gleaton and Lynch, if two distributions are generated from a common baseline distribution by generalized log-logistic transformations, then the log-odds function for one of the distributions is proportional to the log-odds function for the other distribution, with the constant of proportionality being the ratio of the transformation parameters.

Inserting $G(x)$ given in (1.1) into (2.1), we have

$$(2.3) F(x) = \frac{\left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^\alpha}{\left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^\alpha + e^{-\frac{b\alpha}{a}(e^{ax}-1)}}, x > 0.$$

The model of (2.3) is called the OLLGo distribution with parameters α , b and a (we use the notation $X \sim OLLGo(a, b, \alpha)$). Hence, the pdf of OLLGo distribution is

$$(2.4) f(x) = \frac{\alpha b e^{ax} e^{-\frac{b\alpha}{a}(e^{ax}-1)} \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^{\alpha-1}}{\left(\left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^\alpha + e^{-\frac{b\alpha}{a}(e^{ax}-1)}\right)^2}, x > 0.$$

The hazard rate function of OLLGo distribution is given by

$$(2.5) h(x) = \frac{\alpha b e^{ax} \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^{\alpha-1}}{\left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^\alpha + e^{-\frac{b\alpha}{a}(e^{ax}-1)}}, x > 0.$$

The OLLGo distribution includes some well-known distributions such as: $Go(a; b)$ if $\alpha = 1$, which is the generalization of exponential distribution (E) and $OLLE(b; \alpha)$ if a tends to 0^+ . Also, we can state the following propositions related to a OLLGo distribution.

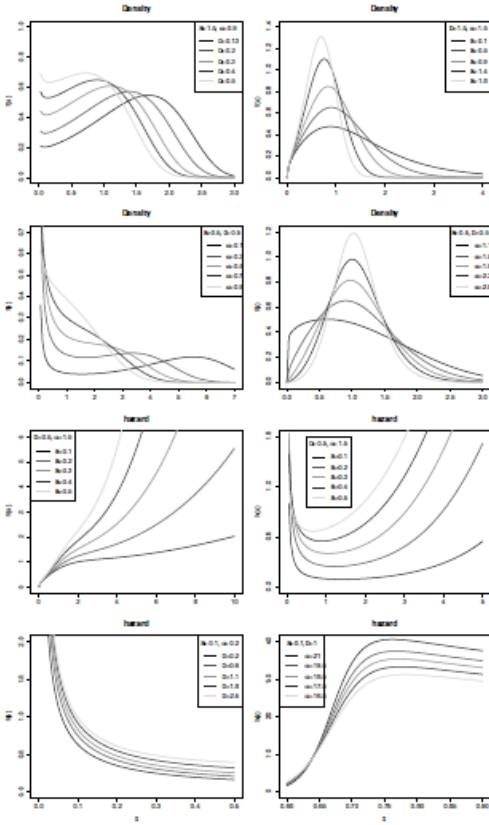

Fig. 1. pdf and hrf of OLL-Go model for some parameter values

PROPOSITION 2.1. Let X have an $OLLGo(\alpha; b; \alpha)$ distribution, then the random variable $Y = 1 - e^{-\frac{b}{\alpha}(e^{aX}-1)}$ satisfies the odd log-logistic unit uniform distribution with parameter α and therefore, the random variable $T = \frac{b}{\alpha}(e^{aX} - 1)$ satisfies the odd log-logistic exponential distribution with parameters α and 1, i.e. $(OLLE(\alpha, 1))$ which is a sub-model of the $OLLGo$ distribution.

PROPOSITION 2.2. If $U \sim U(0, 1)$, then

$$X_u = \frac{1}{a} \log \left\{ 1 - \frac{a}{b} \log \left[\frac{(1 - U)^{\frac{1}{\alpha}}}{U^{\frac{1}{\alpha}} + (1 - U)^{\frac{1}{\alpha}}} \right] \right\},$$

follows $OLLGo(a, b, \alpha)$ distribution.

The result of Proposition 2.2 helps in simulating data from the $OLLGo$ distribution. Figure 1 illustrates some of the possible shapes of density and hazard functions for selected values of the parameters. For instance, these plots show the hazard function of the new model is much more exible than the beta Gompertz (BG) introduced by [22] and Go (Gompertz) distributions. The hazard rate function can be bathtub shaped, monotonically increasing or decreasing and upside-down bathtub shaped depending on the parameter values.

3. General properties

In this section using some existing rules for the power series such as division and multiplication of power series and a power series raised to a positive integer n and so on, some properties of OLLGo distribution are mentioned.

3.1. A useful expansion

First, using generalized binomial expansion we have

$$\begin{aligned} \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^\alpha &= \sum_{i=0}^{\infty} (-1)^i \binom{\alpha}{i} e^{-\frac{ib}{a}(e^{ax}-1)} \\ &= \sum_{i=0}^{\infty} \sum_{k=0}^i (-1)^{i+k} \binom{\alpha}{i} \binom{i}{k} \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^k \\ &= \sum_{i=0}^{\infty} \sum_{k=0}^i (-1)^{i+k} \binom{\alpha}{i} \binom{i}{k} \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^k \\ &= \sum_{k=0}^{\infty} a_k \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^k. \end{aligned}$$

where $a_k = \sum_{i=0}^{\infty} (-1)^{i+k} \binom{\alpha}{i} \binom{i}{k}$. Similarly, we obtain

$$\left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^\alpha + e^{-\frac{b\alpha}{a}(e^{ax}-1)} = \sum_{k=0}^{\infty} b_k \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^k,$$

where $b_k = a_k + (-1)^k \binom{\alpha}{k}$. Now using the rule for division of two power series, we have

$$(3.1) \quad F(x) = \frac{\sum_{k=0}^{\infty} a_k \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^k}{\sum_{k=0}^{\infty} b_k \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^k} = \sum_{k=0}^{\infty} c_k \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^k,$$

where $c_0 = a_0 b_0$ and for $k \geq 1$ we have $c_k = b_0^{-1} [a_k - b_0^{-1} \sum_{r=0}^{k-1} b_r c_{k-r}]$.

The following Propositions show that the cdf and pdf of the OLLGo distribution can be rewritten as a mixture of cdf and pdf of the generalized Gompertz (GG) distributions. The GG distribution was introduced by [11] which has the following cdf and pdf as

$$F(x) = \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^\alpha, \quad a \geq 0, b, \alpha > 0, x \geq 0,$$

and

$$f(x) = \alpha b e^{ax} e^{-\frac{b}{a}(e^{ax}-1)} \left[1 - e^{-\frac{b}{a}(e^{ax}-1)}\right]^{\alpha-1}.$$

PROPOSITION 3.1. The equation (3.1) shows that we can write cdf of OLLGo distribution as a mixture of cdfs of GG distributions as follows:

$$F(x) = \sum_{k=0}^{\infty} c_k H_k(x),$$

where $H_k(x)$ denotes the cdf of GG distribution with power parameter k .

PROPOSITION 3.2. The pdf of OLLGo distribution can be expressed as a mixture of pdfs of GG distributions as follows:

$$(3.2) \quad f(x) = \sum_{k=0}^{\infty} c_{k+1} h_{k+1}(x),$$

where $h_{k+1}(x)$ denotes the pdf of GG distribution with power parameter $k + 1$.

From (3.2), the r th ordinary moment of OLLGo distribution is given by

$$\mu_r = E(X^r) = \sum_{k=0}^{\infty} c_{k+1} E(Y_{k+1}^r),$$

where, using Theorem 2 of [11], the r th moment of Y_{k+1} (a GG random variable with power parameter $k + 1$) can be written as

$$E(Y_{k+1}^r) = (k + 1)b\Gamma(r + 1) \sum_{j=0}^{\infty} \sum_{i=0}^{\infty} \binom{k}{j} \frac{(-1)^{j+i}}{\Gamma(i + 1)} \frac{(e)^{\frac{b}{a}(j+1)}}{\left[\frac{b}{a}(j + 1)\right]^{-i}} \left[\frac{-1}{a(i + 1)}\right]^{r+1}.$$

Therefore, the r th moment of OLLGo distribution is

$$(3.3) \quad \begin{aligned} \mu_r &= E(X^r) \\ &= \sum_{k=0}^{\infty} \sum_{j=0}^{\infty} \sum_{i=0}^{\infty} \binom{k}{j} c_{k+1} (k + 1)b\Gamma(r + 1) \frac{(-1)^{j+i}}{\Gamma(i + 1)} \frac{(e)^{\frac{b}{a}(j+1)}}{\left[\frac{b}{a}(j + 1)\right]^{-i}} \left[\frac{-1}{a(i + 1)}\right]^{r+1}. \end{aligned}$$

The skewness and kurtosis measures can be calculated recursively using the r th moment of OLLGo distribution in (3.3). Furthermore, the cumulants (κ_n) of X can be written recursively as

$$\kappa_n = \mu_n - \sum_{r=1}^{n-1} \binom{n-1}{r-1} \kappa_r \mu_{n-r},$$

where $\kappa_1 = \mu_1, \kappa_2 = \mu_2 - \mu_1^2, \kappa_3 = \mu_3 - 3\mu_1\mu_2 + \mu_1^3$. Figure 2 shows the behaviour of the skewness and kurtosis of OLLGo($a, 1, \alpha$) distribution.

3.2. Moment generating function

We give two representations for moment generating function (mgf) $M(s)$ of the OLLGo distribution. For the first representation, we use the Maclaurin series expansion of an exponential function, as follows

$$M(s) = \sum_{r=0}^{\infty} \frac{s^r}{r!} E(X^r).$$

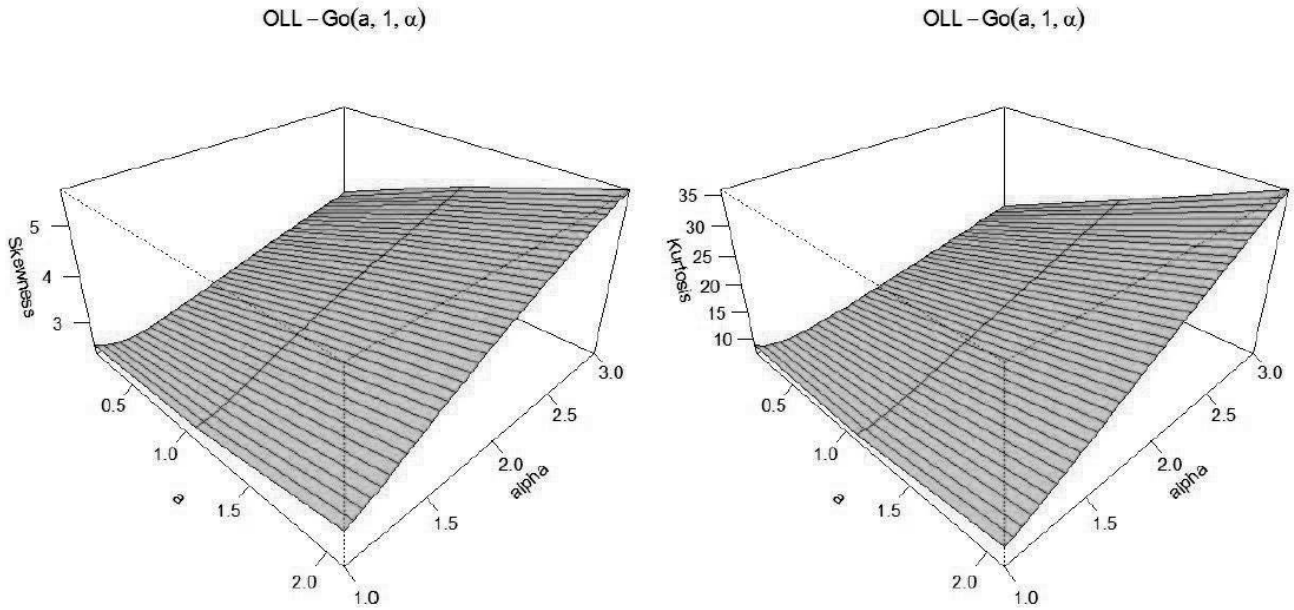

Fig. 2. Skewness and Kurtosis for OLL-Go($a, 1, \alpha$)

Thus the mgf of the $OLLGo(a, b, \alpha)$ distribution can be obtain as

$$M(s) = \sum_{r;k;j;i=0}^{\infty} \binom{k}{j} \frac{s^r}{r!} c_{k+1} (k+1) b \Gamma(r+1) \frac{(-1)^{j+i}}{\Gamma(i+1)} \frac{(e)^{\frac{b}{a}(j+1)}}{\left[\frac{b}{a}(j+1)\right]^{-i}} \left[\frac{-1}{a(i+1)}\right]^{r+1}.$$

For the second representation, using equation (3.2), we can obtain another formula for $M(s)$ as follows:

$$M(s) = \sum_{k=0}^{\infty} c_{k+1} M_{k+1}(s),$$

where

$$M_{k+1}(s) = (k+1) b e^{\frac{b}{a}} \sum_{0}^{\infty} e^{sx} e^{ax} e^{-\frac{b}{a} e^{ax}} \left(1 - e^{-\frac{b}{a} (e^{ax}-1)}\right)^k dx.$$

Using the binomial series expansion for $\left(1 - e^{-\frac{b}{a} (e^{ax}-1)}\right)^k$, we arrive at

$$M_{k+1}(s) = (k+1) b \sum_{j=0}^k \binom{k}{j} (-1)^j e^{\frac{b}{a}(j+1)} \int_0^{\infty} e^{sx} e^{ax} e^{-\frac{b}{a} e^{ax}} e^{-\frac{b}{a} (j+1) e^{ax}} dx.$$

The change of variable $z = e^{ax}$ yields

$$M_{k+1(s)} = \frac{(k+1)b}{a} \sum_{j=0}^k \binom{k}{j} (-1)^j e^{\frac{b}{a}(j+1)} \int_1^{\infty} \frac{s}{z^{\frac{s}{a}}} e^{\frac{b}{a}(j+1)z} dz.$$

Then, setting $y = \frac{b}{a}(j+1)z$, we obtain

$$M_{k+1(s)} = (k+1) \left(\frac{a}{b}\right)^{\frac{s}{a}-1} \sum_{j=0}^k \binom{k}{j} \frac{(-1)^j e^{\frac{b}{a}(j+1)}}{(j+1)^{\frac{s}{a}}} \Gamma\left(\frac{s}{a} + 1, \frac{b}{a}(j+1)\right),$$

where $\Gamma(u, v)$ is the incomplete gamma function defined by

$$\Gamma(u, v) = \int_v^{\infty} x^{u-1} e^{-x} dx.$$

Therefore,

$$M(s) = \sum_{k=0}^{\infty} \sum_{j=0}^k \binom{k}{j} \left(\frac{a}{b}\right)^{\frac{s}{a}-1} \frac{c_{k+1}(k+1)(-1)^j e^{\frac{b}{a}(j+1)}}{(j+1)^{\frac{s}{a}}} \Gamma\left(\frac{s}{a} + 1, \frac{b}{a}(j+1)\right).$$

3.3. Mean deviations

The mean deviations can be used as measures of spread in a population. They are defined by

$$\delta_1 = \int_0^{\infty} |x - \mu| f(x) dx \text{ and } \delta_2 = \int_0^{\infty} |x - M| f(x) dx,$$

where μ and M are the first moment and median of the corresponding distribution. These measures can be expressed as

$$\delta_1 = 2\mu F(\mu) - 2 \int_{\mu}^{\infty} x f(x) dx \text{ and } \delta_2 = \mu - 2 \int_M^{\infty} x f(x) dx.$$

Using the above equations we obtain closed form formulas for δ_1 and δ_2 . From (3.2), we have

$$h_{GG}(x; a, b, k+1) = (k+1) b e^{ax} e^{-\frac{b}{a}(e^{ax}-1)} \left(1 - e^{-\frac{b}{a}(e^{ax}-1)}\right)^k,$$

and then for a given η we have

$$\int_{\eta}^{\infty} x f(x) dx = \frac{b}{a^2} \sum_{k=0}^{\infty} \sum_{j=0}^k \binom{k}{j} (-1)^j (k+1) c_{k+1} e^{\frac{(j+1)b}{a}} \int_{e^{a\eta}}^{\infty} e^{-\frac{b}{a}(j+1)z} \ln(z) dz.$$

Upon changing variables and integrating by parts we have

$$\begin{aligned} \int_{\eta}^{\infty} xf(x)dx &= \frac{b}{a^2} \sum_{k=0}^{\infty} \sum_{j=0}^k \binom{k}{j} (-1)^j (k+1) c_{k+1} e^{\frac{(j+1)b}{a}} \left[\frac{a\eta e^{-\frac{b}{a}(j+1)e^{a\eta}}}{\frac{b}{a}(j+1)} + \frac{\Gamma\left(0, \frac{b}{a}(j+1)e^{a\eta}\right)}{\frac{b}{a}(j+1)} \right] \\ &= \frac{1}{a} \sum_{k=0}^{\infty} \sum_{j=0}^k \binom{k}{j} \frac{(-1)^j (k+1) c_{k+1} e^{\frac{(j+1)b}{a}}}{(j+1)} \left[a\eta e^{-\frac{b}{a}(j+1)e^{a\eta}} + \Gamma\left(0, \frac{b}{a}(j+1)e^{a\eta}\right) \right]. \end{aligned}$$

Therefore,

$$\delta_1 = 2\mu F(\mu) - \frac{2}{a} \sum_{k=0}^{\infty} \sum_{j=0}^k \binom{k}{j} \frac{(-1)^j (k+1) c_{k+1} e^{\frac{(j+1)b}{a}}}{(j+1)} \left[\mu a e^{-\frac{b}{a}(j+1)e^{a\mu}} + \Gamma\left(0, \frac{b}{a}(j+1)e^{a\mu}\right) \right],$$

and

$$\delta_2 = \mu - \frac{2}{a} \sum_{k=0}^{\infty} \sum_{j=0}^k \binom{k}{j} \frac{(-1)^j (k+1) c_{k+1} e^{\frac{(j+1)b}{a}}}{(j+1)} \left\{ M a e^{-\frac{b}{a}(j+1)e^{aM}} + \Gamma\left(0, \frac{b}{a}(j+1)e^{aM}\right) \right\}.$$

3.4. Order Statistics

Order statistics make their appearance in many areas of statistical theory and practice. Suppose X_1, \dots, X_n is a random sample from any OLLGo distribution. Let $X_{i:n}$ denote the i th order statistic. The pdf of $X_{i:n}$ can be expressed as

$$f_{i:n}(x) = c f(x) F^{i-1}(x) \{1 - F(x)\}^{n-i} = c \sum_{j=0}^{n-i} (-1)^j \binom{n-i}{j} f(x) F(x)^{j+i-1},$$

where $c = \frac{1}{B(i, n-i+1)}$.

Upon integration, the cdf of i th order statistic is

$$F_{i:n}(x) = c \sum_{j=0}^{n-i} \frac{(-1)^j}{j+i} \binom{n-i}{j} F(x)^{j+i}.$$

From Gradshteyn and Ryzhik (2000), we can use the following expansion for a power series raise to a positive integer as

$$\left(\sum_{i=0}^{\infty} a_i u^i \right)^n = \sum_{i=0}^{\infty} c_{n,i} u^i; \quad n \geq 1,$$

where the coefficients $c_{n,i}$ (for $i = 1, 2, \dots$) are determined from the recurrence equation (with $c_{n,0} = a_0^n$)

$$(3.4) \quad c_{n,i} = (i a_0)^{-1} \sum_{m=1}^i [m(n+1) - i] a_m c_{n,i-m}.$$

Applying the above equations to the power series form of the $F(x)^{j+i}$ with $F(x)$ given by (3.1), the cdf of i th order statistic from OLLGo distribution can be rewritten as

$$F_{i:m}(x) = c \sum_{j=0}^{n-i} \sum_{k=0}^{\infty} e_{i,j} c_{i+j,k} H_k(x),$$

where $e_{i,j} = \frac{(-1)^j}{j+i} \binom{n-i}{j}$, $c_{i+j,0} = c_0^{i+j}$ and $c_{i+j,k}$ satisfy in the following recursive equation

$$c_{i+j,k} = (kc_0)^{-1} \sum_{m=1}^k [m(i+j+1) - k] c_m c_{i+j,k-m}.$$

The pdf of the i th order statistic can be used to obtain the moments, mgf and mean deviations of the OLLGo order statistics from above equations and some properties of the GG model.

3.5. Asymptotics and shapes

In the following Proposition we give some asymptotes for cdf, pdf and hazard rate functions of the OLLGo model.

PROPOSITION 3.3. Let the random variable X have OLLGo($a; b; \alpha$) distribution with cdf $F(x)$, pdf $f(x)$ and failure rate function $h(x)$, then,

$$F(x) \sim (bx)^\alpha \text{ as } x \rightarrow 0,$$

$$f(x) \sim \alpha b^\alpha x^{\alpha-1} \text{ as } x \rightarrow 0,$$

$$h(x) \sim \alpha b^\alpha x^{\alpha-1} \text{ as } x \rightarrow 0,$$

$$1 - F(x) \sim e^{\frac{-b}{a}} e^{ax} \text{ as } x \rightarrow 1,$$

$$f(x) \sim b \alpha e^{ax} e^{\frac{-b\alpha}{a}} e^{ax} \text{ as } x \rightarrow 1;$$

$$h(x) \sim b \alpha e^{ax} \text{ as } x \rightarrow 1;$$

These equations show the effect of parameters on the tail of OLLGo distribution.

3.6. Quantile measure

The quantile function of OLLGo distribution is given by

$$Q(u) = \frac{1}{a} \log \left\{ 1 - \frac{a}{b} \log \frac{(1-u)^{\frac{1}{\alpha}}}{u^{\frac{1}{\alpha}} + (1-u)^{\frac{1}{\alpha}}} \right\},$$

where $u \in (0, 1)$.

4. Characterization Results

This section deals with the characterizations of the OLLGo distribution in different directions: (i) based on the ratio of two truncated moments; (ii) in terms of the hazard function; (iii) in terms of the reverse hazard function and (iv) based on the conditional expectation of a function of the random variable. Note that (i) can be employed also when the cdf does not have a closed form. We would also

like to mention that due to the nature of OLLGo distribution, our characterizations may be the only possible ones. We present our characterizations (i)-(iv) in four subsections.

4.1. Characterizations based on two truncated moments

This subsection is devoted to the characterizations of OLLGo distribution based on the ratio of two truncated moments. Our first characterization employs a theorem due to Glänzel (1987), see Theorem 1 of Appendix A. The result, however, holds also when the interval H is not closed, since the condition of the Theorem is on the interior of H .

PROPOSITION 4.1. *Let $X: \Omega (0, \infty)$ be a continuous random variable and let*

$$q_1(x) = \left(\left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right] + e^{-\frac{b}{a}(e^{ax-1})} \right)^2$$

and

$$q_2(x) = q_1(x) \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^\alpha$$

for $x > 0$. The random variable X has pdf (2.4) if and only if the function η defined in Theorem 1 is of the form

$$\eta(x) = \frac{1}{2} \left\{ 1 + \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^\alpha \right\}, \quad x > 0.$$

PROOF. Suppose the random variable X has pdf (2.4), then

$$(1 - F(x))E[q_1(X) | X \geq x] = 1 - \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^\alpha, \quad x > 0,$$

and

$$(1 - F(x))E[q_2(X) | X \geq x] = \frac{1}{2} \left\{ 1 - \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^{2\alpha} \right\}, \quad x > 0.$$

Further,

$$\eta(x)q_1(x) - q_2(x) = \frac{q_1(x)}{2} \left\{ 1 - \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^\alpha \right\} > 0, \quad \text{for } x > 0:$$

Conversely, if η is of the above form, then

$$s'(x) = \frac{\eta'(x)q_1(x)}{\eta(x)q_1(x) - q_2(x)} = \frac{\alpha b e^{ax} e^{-\frac{b}{a}(e^{ax-1})} \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^{\alpha-1}}{1 - \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^\alpha}, \quad x > 0,$$

and consequently

$$s(x) = -\log \left\{ \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^\alpha \right\}, \quad x > 0.$$

Now, according to Theorem 1, X has density (2.4).

COROLLARY 4.1. Let $X: \Omega (0, \infty)$ be a continuous random variable and let $q_1(x)$ be as in Proposition 4.1. The random variable X has pdf (2.4) if and only if there exist functions q_2 and η defined in Theorem 1 satisfying the following differential equation

$$\frac{\eta'(x)q_1(x)}{\eta(x)q_1(x) - q_2(x)} = \frac{\alpha b e^{ax} e^{-\frac{b}{a}(e^{ax-1})} \left[1 - e^{-\frac{b}{a}(e^{ax-1})}\right]^{\alpha-1}}{1 - \left[1 - e^{-\frac{b}{a}(e^{ax-1})}\right]^{\alpha}}, \quad x > 0.$$

COROLLARY 4.2. The general solution of the differential equation in Corollary 4.1 is

$$\eta(x) = \left\{1 - \left[1 - e^{-\frac{b}{a}(e^{ax-1})}\right]^{\alpha}\right\}^{-1} \times \left[-\int \alpha b e^{ax} e^{-\frac{b}{a}(e^{ax-1})} \left[1 - e^{-\frac{b}{a}(e^{ax-1})}\right]^{\alpha-1} (q_1(x))^{-1} q_2(x) dx + D\right],$$

where D is a constant. We like to point out that one set of functions satisfying the above differential equation is given in Proposition 4.1 with $D = \frac{1}{2}$. Clearly, there are other triplets (q_1, q_2, η) which satisfy conditions of Theorem 1.

4.2. Characterization in terms of hazard function

The hazard function, h_F , of a twice differentiable distribution function, F , satisfies the following first order differential equation

$$\frac{f'(x)}{f(x)} = \frac{h'_F(x)}{h_F(x)} - h_F(x).$$

It should be mentioned that for many univariate continuous distributions, the above equation is the only differential equation available in terms of the hazard function. In this subsection we present non-trivial characterizations of OLLGo distribution, for $\alpha = 1$, in terms of the hazard function.

PROPOSITION 4.2. Let $X: \Omega (0, \infty)$ be a continuous random variable. The random variable X has pdf (2.4), for $\alpha = 1$, if and only if its hazard function $h_F(x)$ satisfies the following differential equation

$$h'_F(x) - ah_F(x) = 0, \quad x > 0.$$

PROOF. The proof is straightforward and hence omitted. _

4.3. Characterization in terms of the reverse hazard function

The reverse hazard function, r_F , of a twice differentiable distribution function, F , is defined as

$$r_F(x) = \frac{f(x)}{F(x)}, x \in \text{support of } F.$$

In this subsection we present a characterization of OLLGo distribution in terms of the reverse hazard function.

PROPOSITION 4.3. Let $X: \Omega (0, \infty)$ be a continuous random variable. The random variable X has pdf (2.4) if and only if its reverse hazard function $r_F(x)$ satisfies the following differential equation

$$r'_F(x) + be^{ax}r_F(x) = abe^{-\frac{b}{a}(e^{ax-1})} \frac{d}{dx} \left\{ \frac{e^{ax} \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^{-1}}{\left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^\alpha + e^{-\frac{b\alpha}{a}(e^{ax-1})}} \right\}, \quad x > 0.$$

PROOF. If X has pdf (2.4), then clearly the above differential equation holds. Now, if this equation holds, then

$$\frac{d}{dx} \left\{ e^{\frac{b}{a}(e^{ax-1})} r_F(x) \right\} = ab \frac{d}{dx} \left\{ \frac{e^{ax} \left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^{-1}}{\left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^\alpha + e^{-\frac{b\alpha}{a}(e^{ax-1})}} \right\},$$

from which we obtain the reverse hazard function corresponding to the pdf (2.4).

REMARK 4.1. For $\alpha = 1$, the above differential equation has the following much simpler form.

$$r'_F(x) + be^{ax}r_F(x) = be^{ax-\frac{b}{a}(e^{ax-1})} \left\{ \frac{a - e^{-\frac{b}{a}(e^{ax-1})} [a - be^{ax}]}{\left[1 - e^{-\frac{b}{a}(e^{ax-1})} \right]^2} \right\}, \quad x > 0.$$

4.4. Characterization based on the conditional expectation of certain function of the random variable

In this subsection we employ a single function ψ of X and characterize the distribution of X in terms of the truncated moment of $\psi(X)$. The following proposition has already appeared in Hamedani's previous work (2013), so we will just state it here. It can be used to characterize an OLLGo distribution for $\alpha = 1$.

PROPOSITION 4.4. Let $X: \Omega (e; f)$ be a continuous random variable with cdf F . Let $\psi(x)$ be a differentiable function on $(e; f)$ with $\lim_{x \rightarrow e^+} \psi(x) = 1$. Then for $\delta \neq 1$,

$$E[\psi(X) | X \geq x] = \delta\psi(x), x \in (e, f)$$

if and only if

$$\psi(x) = (1 - F(x))^{\frac{1}{\delta}-1}, \quad x \in (e; f).$$

REMARK 4.2. For $(e, f) = (0, \infty)$, $\alpha = 1$, $\psi(x) = e^{-(e^{ax-1})}$ and $\delta = \frac{b}{a+b}$, Proposition 4.4 provides a characterization of OLLGo for $\alpha = 1$.

5. Estimation

Let X_1, \dots, X_n be a random sample of size n from the $OLLGo(a; b; \alpha)$ distribution and $\Theta = (a; b; \alpha)$ be the unknown parameter vector. The loglikelihood function is given by

$$l(\Theta) = n \log(ab) + a \sum_{i=1}^n x_i + \alpha \sum_{i=1}^n \log(1 - t_i) + (\alpha - 1) \sum_{i=1}^n \log(t_i) - 2 \sum_{i=1}^n \log(t_i^\alpha + (1 - t_i)^\alpha),$$

where $t_i = 1 - \exp(-\frac{b}{a}(e^{ax_i} - 1))$. The maximum likelihood estimation (MLE) of θ is obtained by solving the nonlinear equations, $U(\Theta) = (U_a(\Theta); U_b(\Theta); U_\alpha(\Theta))^T = \mathbf{0}$, where

$$U_\alpha(\Theta) = \frac{\partial l(\Theta)}{\partial \alpha} = \frac{n}{\alpha} + \sum_{i=1}^n \log(t_i(1 - t_i)) - 2 \sum_{i=1}^n \frac{t_i^\alpha \log t_i + (1 - t_i)^\alpha \log(1 - t_i)}{t_i^\alpha + (1 - t_i)^\alpha},$$

$$U_a(\Theta) = \frac{\partial l(\Theta)}{\partial a} = n\bar{x} - \alpha \sum_{i=1}^n \frac{t_i^{(a)}}{1 - t_i} + (\alpha - 1) \sum_{i=1}^n \frac{t_i^{(a)}}{t_i} - 2\alpha \sum_{i=1}^n t_i^{(a)} \times \frac{t_i^{\alpha-1} - (1 - t_i)^{\alpha-1}}{t_i^\alpha + (1 - t_i)^\alpha},$$

$$U_b(\Theta) = \frac{\partial l(\Theta)}{\partial b} = \frac{n}{b} - \alpha \sum_{i=1}^n \frac{t_i^{(b)}}{1 - t_i} + (\alpha - 1) \sum_{i=1}^n \frac{t_i^{(b)}}{t_i} - 2\alpha \sum_{i=1}^n t_i^{(b)} \times \frac{t_i^{\alpha-1} - (1 - t_i)^{\alpha-1}}{t_i^\alpha + (1 - t_i)^\alpha}.$$

Note that

$$t_i^{(a)} = \frac{\partial t_i}{\partial a} = \left(-\frac{bx_i}{a} e^{ax_i} \frac{b}{a^2} (e^{ax_i} - 1)\right)(1 - t_i)$$

and

$$t_i^{(b)} = \frac{\partial t_i}{\partial b} = \frac{1}{a}(e^{ax_i} - 1)(1 - t_i).$$

By Referring to Gleaton and Rahman (2010, 2014), there are situations in which some of the regularity conditions are not necessarily satisfied for certain subsets of the interior of the parameter space for certain GLL-families of distributions. We will check these regularity conditions for this proposed distribution OLLGo in our future work. So, by assuming that the regularity conditions hold then asymptotically

$$n(\hat{\Theta} - \Theta) \sim N_3(0, I(\Theta)^{-1}),$$

where $I(\Theta)$ is the expected Fisher information matrix. This asymptotic behavior is valid if $I(\Theta)$ replaced by $J_n(\hat{\Theta})$, i.e., the observed Fisher information matrix evaluated at $\hat{\Theta}$, see [9].

5.1. The other estimation methods

There are several approaches to estimating the parameters of distributions, and each of them has its characteristic features and benefits. In this subsection, three of these methods are briefly mentioned and numerically investigated in the simulation study. A useful summary of these methods can be found in Dey *et al.* (2017). Here $\{t_{i:n}; i = 1, 2, \dots, n\}$ is the associated order statistics and F is the distribution function of OLLGo distribution.

5.1.1. Weighted least square estimators

The Weighted least square estimators (WLSE) was introduced by Swain *et al.* (1988). The WLSE's is obtained by minimizing

$$S_{WLSSE}(a, b, \alpha) = \sum_{i=1}^n \frac{(n+1)^2(n+2)}{i(n-i+1)} \left(F(t_{i:n}; a, b, \alpha) - \frac{i}{n+1} \right)^2$$

with respect to a, b and α .

5.1.2. Cramr-von-Mises estimator

Cramér-von-Mises Estimator (CVM) was introduced by Choi and Bulgren (1968). The CVMs is obtained by minimizing the following function

$$S_{CVM}(a, b, \alpha) = \frac{1}{12n} + \sum_{i=1}^n \left(F(t_{i:n}; a, b, \alpha) - \frac{2i-1}{2n} \right)^2.$$

5.1.3. Anderson-Darling and right-tailed Anderson-Darling estimators

The Anderson Darling (ADE) and Right-tailed Anderson Darling estimators (RTADE) were introduced by Anderson and Darling (1952). The ADE's and RTADE's are obtained by minimizing with respect to a, b and α , the function

$$S_{ADE}(a, b, \alpha) = -n - \frac{1}{n} \sum_{i=1}^n (2i-1) \{ \log F(t_{i:n}; a, b, \alpha) + \log \bar{F}(t_{i:n}; a, b, \alpha) \},$$

where $\bar{F}(\cdot) = 1 - F(\cdot)$.

6. Simulation study

In this subsection, the behaviour of the MLEs of the parameters of the OLLGo distribution has been assessed via simulation. To verify the validity of the MLEs, the bias and the mean square error (MSE) of MLEs have been checked. Samples of size $n = 20, 25, \dots, 200$, from $OLLGo(a, b, \alpha) = (2, 0.05, 1.1)$, with $(a, b, \alpha) = (2, 0.05, 1.1)$ have been generated. To estimate the MLEs, the *optim* function (in the *stat* package) and BFGS method in R software have been used. We replicate these steps for $r = 200$ times. If $\xi = (a, b, \alpha)$, for the i th replication $i = 1, 2, \dots, 200$ the MLEs are obtained as $\hat{\xi}_i = (\hat{a}_i, \hat{b}_i, \hat{\alpha}_i)$. We Compute the biases and MSEs as

(6.1)

$$Bias_r(\widehat{\xi}) = \frac{1}{r} \sum_{i=1}^r (\hat{\xi}_i - \xi_i), \quad \text{and} \quad MSE_r(\widehat{\xi}) = \frac{1}{r} \sum_{i=1}^r (\hat{\xi}_i - \xi_i)^2, \quad \text{for } \xi = (a, b, \alpha).$$

Figures 3, 4 respectively reveal how the three biases, MSEs vary with respect to n . As expected, the Biases and MSEs of the estimated parameters converge to zero while n growing.

Fig. 3. Bias of \hat{a} , \hat{b} , $\hat{\alpha}$ versus n for OLLGo when $(a, b, \alpha) = (2, 0.05, 1.1)$

In order to explore the estimators introduced above, we consider one model that has been used in this section and investigate MSE of estimators for different samples. We consider the sample sizes of the $n = 30, 35, \dots, 200$ with $r = 200$ replications and we take $(a, b, \alpha) = (2, 0.05, 1.1)$. Then the biases and MSEs formulas that are mentioned in equation (6.1) are calculated.

Fig. 4. MSE of \hat{a} , \hat{b} , $\hat{\alpha}$ versus n for OLLGo when $(a, b, \alpha) = (2, 0.05, 1.1)$

To obtain the value of the estimators, we have used the optima function and BFGS method in R, again. The results of the simulations of this subsection are shown in Figures (5) and (6).

A general result about above figures is that MSE plots for three parameters (a, b, α) will approach zero as the sample size increases for all methods WLSE, CVM, and ADE and this verifies the validity of the these estimation methods and numerical calculations for the parameters of OLLGo distribution. Further results are mentioned below

- For estimating a , ADE method has the minimum amount of bias.
- For estimating b , ADE method has the minimum amount of bias.
- For estimating α , ADE method has the minimum amount of bias.
- For estimating a , ADE method has the minimum amount of MSE.
- For estimating b , ADE method has the minimum amount of MSE.
- For estimating α , ADE method has the minimum amount of MSE.

7. Application of OLLG to real data set

The following data set have been obtained from [1] and represents the lifetimes of 50 devices. The data are:

0.1, 0.2, 1.0, 1.0, 1.0, 1.0, 1.0, 2.0, 3.0, 6.0, 7.0, 11.0, 12.0, 18.0, 18.0, 18.0, 18.0, 18.0, 21.0, 32.0, 36.0, 40.0, 45.0, 45.0, 47.0, 50.0, 55.0, 60.0, 63.0, 63.0, 67.0, 67.0, 67.0, 67.0, 72.0, 75.0, 79.0, 82.0, 82.0, 83.0, 84.0, 84.0, 84.0, 85.0, 85.0, 85.0, 85.0, 85.0, 86.0, 86.0.

To analyze above data, we obtained the MLE's of the parameters (with standard deviations) for the distributions OLLGo (proposed distribution in this paper), OLLE ([27]), Go (Gompertz distribution), MO-EGG (Marshal-Olkin extended generalized Gompertz) introduced by [4]), Beta-Go (Beta-Gompertz introduced by [22]), Mc-Go (Mc Donald-Gompertz introduced by [29]), Kw-Go (Kumaraswamy

Gompertz introduced by [31]) and GGo (generalized Gompertz introduced by [11]). Then, we calculated the Akaike information

Fig. 6. MSE of $\hat{a}, \hat{b}, \hat{\alpha}$ versus n for OLLGo when $(a, b, \alpha) = (2, 0.05, 1.1)$ for WLSE, CVM, and ADE methods

criterion (AIC), Bayesian information criterion (BIC), Anderson-Darling (AC) and Cramér-von Mises (W^*), Kolmogorov Smirnov (K-S) statistic and the P-Value of K. S test for each model. The results show that the OLLGo distribution yields the best fit. The plots of the densities (together with the data histogram) and cumulative distribution functions in Figure 7 confirm this conclusion.

8. Conclusion

Here we propose a new model, called the OLLGo distribution. Some mathematical properties of this model including explicit expansions for the ordinary and incomplete moments, quantile and mgf, mean deviations, and

	Distribution

9. Appendix A.

THEOREM 1. Let $(\Omega, \mathcal{F}; \mathbf{P})$ be a given probability space and let $H = [a, b]$ be an interval for some $d < b$ ($a = -\infty, b = \infty$ might as well be allowed). Let $X : \Omega \rightarrow H$ be a continuous random variable with the distribution function F and let q_1 and q_2 be two real functions defined on H such that

$$E[q_2(X) | X \geq x] = E[q_1(X) | X \geq x]\eta(x); \quad x \in H,$$

is defined with some real function η . Assume that $q_1, q_2 \in C^1(H), \xi \in C^2(H)$ and F is twice continuously differentiable and strictly monotone function on the set H . Finally, assume that the equation $\eta q_1 = q_2$ has no real solution in the interior of H . Then F is uniquely determined by the functions q_1, q_2 and η , particularly

$$F(x) = \int_a^x C \left| \frac{\eta'(u)}{(u)q_1(u) - q_2(u)} \right| \exp(-s(u)) du,$$

where the function s is a solution of the differential equation $s' = \frac{\eta'q_1}{\eta q_1 - q_2}$ and C is the normalization constant, such that $\int_H dF = 1$.

We like to mention that this kind of characterization based on the ratio of truncated moments is stable in the sense of weak convergence (see, Glänzel [14]), in particular, let us assume that there is a sequence $\{X_n\}$ of random variables with distribution functions $\{F_n\}$ such that the functions q_{1n}, q_{2n} and η_n ($n \in \mathbb{N}$) satisfy the conditions of Theorem 1 and let $q_{1n} \rightarrow q_1, q_{2n} \rightarrow q_2$ for some continuously differentiable real functions q_1 and q_2 . Let, finally, X be a random variable with distribution F . Under the condition that $q_{1n}(X)$ and $q_{2n}(X)$ are uniformly integrable and the family $\{F_n\}$ is relatively compact, the sequence X_n converges to X in distribution if and only if η_n converges to η , where

$$\eta(x) = \frac{E[q_2(X) | X \geq x]}{E[q_1(X) | X \geq x]}.$$

This stability theorem makes sure that the convergence of distribution functions is reflected by corresponding convergence of the functions q_1, q_2 and η , respectively. It guarantees, for instance, the 'convergence' of characterization of the Wald distribution to that of the Lévy-Smirnov distribution if $\alpha \rightarrow \infty$.

A further consequence of the stability property of Theorem 1 is the application of this theorem to special tasks in statistical practice such as the estimation of the parameters of discrete distributions.

For such purpose, the functions q_1 , q_2 and, specially, η should be as simple as possible. Since the function triplet is not uniquely determined it is often possible to choose η as a linear function. Therefore, it is worth analyzing some special cases which helps to find new characterizations reflecting the relationship between individual continuous univariate distributions and appropriate in other areas of statistics.
