Future Perspectives

Exercise and lifestyle physical activity recommendations for people with multiple sclerosis throughout the disease course

Abstract

Objectives: To provide clinicians who treat multiple sclerosis (MS) patients with evidence-based or expert opinion–based recommendations for promoting exercise and lifestyle physical activity across disability levels.

Methods: The National MS Society (“Society”) convened clinical and research experts in the fields of MS, exercise, rehabilitation, and physical activity to (1) reach consensus on optimal exercise and lifestyle physical activity recommendations for individuals with MS at disability levels 0–9.0 on the Expanded Disability Status Scale (EDSS) and (2) identify and address barriers/facilitators for participation.

Recommendations: Based on current evidence and expert opinion, the Society makes the following recommendations, endorsed by the Consortium of Multiple Sclerosis Centers:

- Healthcare providers should endorse and promote the benefits/safety of exercise and lifestyle physical activity for every person with MS.
- Early evaluation by a physical or occupational therapist or exercise or sport scientist, experienced in MS (hereafter referred to as “specialists”), is recommended to establish an individualized exercise and/or lifestyle physical activity plan.
- Taking into account comorbidities and symptom fluctuations, healthcare providers should encourage ≥150 min/week of exercise and/or ≥150 min/week of lifestyle physical activity.
- Progress toward these targets should be gradual, based on the person’s abilities, preferences, and safety.
- If disability increases and exercise/physical activity becomes more challenging, referrals to specialists are essential to ensure safe and appropriate prescriptions.
- When physical mobility is very limited, exercise should be facilitated by a trained assistant.

Keywords: Multiple sclerosis, exercise, physical activity, lifestyle physical activity, recommendations, wellness, disability

Date received: 18 November 2019; revised: 29 February 2020; accepted: 4 March 2020.

Introduction

Wellness is a priority for people with multiple sclerosis (MS) and can be achieved through health behaviors including physical activity and exercise. Exercise, including lifestyle physical activity and exercise, comprises any bodily movement produced by skeletal muscle contraction that results in a substantial increase in energy expenditure over resting levels. Lifestyle physical activity is the daily accumulation of at least 30 minutes of activities, including all planned or unplanned leisure, occupational, or household activities that are at least moderate to vigorous in their intensity. Exercise is a form of leisure-time physical activity that is usually performed repeatedly over an extended period of time (exercise training) with a specific external objective (e.g. improvement of fitness, physical performance, or health).
These activities are distinct from rehabilitation, which is defined as intermittent or ongoing use of interdisciplinary strategies to regain or maintain optimal physical function, promote functional independence, prevent complications, and improve overall quality of life.7

Meta-analyses and systematic reviews of randomized controlled trials have demonstrated that people with MS who engage in exercise and lifestyle physical activity experience benefits from immune cell through quality-of-life outcomes.8,9 Furthermore, exercise and lifestyle physical activity are safe for people with MS.10 While initial studies established exercise as an effective symptomatic treatment (tertiary prevention), more recent studies have evaluated the disease-modifying effects (secondary prevention) as well as the impact on the risk of developing MS (primary prevention)—explaining why exercise and physical activity have been suggested as “medicine in MS.”11

Unfortunately, MS patients are much less active than healthy controls.12,13 One recent review by an international panel of experts highlighted the opportunity for neurologists, advanced practice clinicians, and primary care providers to promote exercise and physical activity in their patients,9 and a recent study demonstrated that adherence to a physical activity program is higher when referral is made by a physician.14 Yet, qualitative research indicates that many providers lack the expertise to do so.15

This paper offers clinicians specific exercise and lifestyle physical activity recommendations—evidence-based when possible, and expert opinion where published data are lacking—for their patients at all levels of disability. The recommendations are tailored by disability level using the Kurtzke Expanded Disability Status Scale (EDSS)—a method of measuring neurologic disability in MS (see Figure 1 in Supplemental Appendix 1).16 Levels 0–9.0 (ranging from no disability to confined to bed) are considered in this paper.

Recommendations for the intensity of exercise/physical activity are based in part on an individual’s perceived exertion level (subjective evaluation of intensity, effort, strain, discomfort, and/or fatigue during exercise). See Table 1a in Supplemental Appendix 1 for use of Borg’s Rating of Perceived Exertion (RPE).17,18

**Methodology**
The National MS Society convened international experts in the fields of MS, exercise, rehabilitation, and physical activity (physicians, nurses, physical therapists, occupational therapists, exercise scientists, community health professionals) to (1) review the literature and reach consensus on optimal exercise and lifestyle physical activity recommendations for individuals with MS across major categories of disability on the EDSS and (2) identify and address barriers and facilitators of participation. The group used published exercise and physical activity guidelines as the starting point, supplemented by additional high-quality studies and expert opinion, particularly at the higher disability levels where evidence has been lacking. Sub-teams were created for three EDSS ranges corresponding to MS with mild impairments (0–4.5), MS characterized by greater mobility impairment (5.0–6.5), and MS characterized by diminished ability to carry out activities of daily living (7.0–9.0)—which are consistent with ranges used in the literature (see Figure 1 in Supplemental Appendix 1). Following a review of the recent literature, evidence-based and expert recommendations were created.

**Exercise and lifestyle physical activity recommendations throughout the disease course**
To assist clinicians who are unfamiliar with the EDSS, Table 1 provides clinical descriptors for each disability range. Tables 2 and 3 provide exercise and lifestyle physical activity recommendations, respectively, as well as key messages for individuals in those disability ranges. The recommendations reflect the minimum exercise and lifestyle physical activity targets for people with MS; however, each individual’s starting point and rate of progress toward a target will differ. As disability increases and mobility becomes more challenging, so does the importance of personalized recommendations and guidance by a trained rehabilitation or exercise professional. For that reason, the EDSS level 7.0–9.0 has been sub-divided to allow for more specific recommendations for individuals with the highest levels of disability.

**Barriers and facilitators to exercise and lifestyle physical activity**
Table 4 presents the types of barriers that may reduce a person’s ability to engage in exercise and lifestyle physical activity, as well as the facilitators that can increase a person’s ability to do so.15

**Discussion**
Despite ample evidence demonstrating the benefits of exercise and lifestyle physical activity for people with...
Table 1. Clinical descriptors for EDSS ranges 0–4.5, 5.0–6.5, and 7.0–9.0.

**EDSS 0–4.5**
- Symptoms: Ranging from no symptoms to mild-to-moderate fatigue, unsteadiness/imbalance, sensory changes, mild walking impairment, and reduced visual acuity; bowel and/or bladder symptoms; altered mood state; and cognitive impairment
- Neurologic impairments: Ranging from normal neurologic exam to mild-to-moderate impairments in proprioception, cerebellar function, vision, muscle strength/tone/endurance, bladder function, and cognition
- Functional limitations: Ranging from no limitations to limited endurance, unsteadiness, and impaired information processing and memory

**EDSS 5.0–6.5**
- Symptoms: Progression of any or all symptoms mentioned above
- Neurologic impairments: May include an increase in the impairments mentioned above, worsening gait (unilateral to bilateral spastic paresis, foot drop with compensatory hip hike, and circumduction with progression from unilateral to bilateral assistance and/or use of manual wheelchair), and upper extremity coordination
- Functional limitations: Limited walking distance (20–200 m); falls; inability to safely complete dual motor/cognitive tasks; work/home activities require adaptions, compensatory strategies, and mobility aids (ranging from cane to wheeled walker for daily use to a manual wheelchair for distances); transfers on/off the floor and into/out of chairs increasingly challenging; and requires assistance from support partner for more complex daily activities

**EDSS 7.0–9.0**
- Symptoms: Continued worsening of all symptoms mentioned above
- Neurologic impairments: Significant impairments in many or all systems, as mentioned above
- Functional limitations: Gait—from 10 ft with a walker to restricted to bed and wheelchair; Transfers—from minimal assist to total assist; Bed mobility—from minimal assist to total assist; Seated balance—from independent to total assist; Standing balance—from independent with bilateral support to unable to stand unaided

EDSS: Expanded Disability Status Scale.

MS, MS patients continue to be substantially less active than their counterparts in the general population. Many people with MS doubt their ability to be physically active. Fatigue, mobility impairment, depression, fears about safety, reluctance to engage in activities they cannot do as easily or well as they did them before, and lack of access to appropriate venues are just a few possible reasons for their inactivity. Neurologists, advance practice clinicians, and other healthcare providers can be powerful advocates for exercise and physical activity, emphasizing the benefits for disease and symptom management, overall health, and quality of life, and assuring their patients that it will not worsen their MS. Healthcare providers are encouraged to:

- Ask routinely about a patient’s exercise and physical activity habits
- Offer timely information about how and why to be physically active (benefits and expected outcomes) as well as guidance about exercise equipment, accessible exercise facilities, and transportation
- Suggest strategies to increase self-efficacy, accountability, planning and goal-setting, and self-monitoring, to help the person sustain her or his exercise and lifestyle physical activities.

Experts in the field are urged to collaborate with the National MS Society and other advocacy organizations to create, evaluate, and disseminate the materials needed by healthcare professionals to fulfill this role.

Every patient can benefit from guidance that is tailored to her or his needs, abilities, and preferences. To that end, recommendations for exercise and physical activity should include a range of options that take into account individual differences at every level of disability. While individuals with mild disability may continue to be as physically active as they always have, they may benefit from training by specialists in fatigue and energy management, and in ways to adapt their favorite activities to meet their needs. As the disease progresses and engaging in exercise and physical activity becomes more challenging, referrals to specialists are essential for ensuring that patients’ exercise and physical activity strategies are individualized to best meet their needs. For these professionals to offer optimal interventions, the existing gaps in our knowledge must be filled by additional research—particularly at higher levels of disability. In the meantime, the expert recommendations in this paper complement the

<tr>
<td>• Exercise is beneficial even if a person must do it differently than in the past</td>
<td>• Exercise is possible for people with increasing disability</td>
<td>• At this level of disability, all recommendations are expert opinion except where noted, due to lack of published evidence</td>
</tr>
<tr>
<td>• Referrals to exercise specialists/programs for individuals with chronic conditions can facilitate participation</td>
<td>• When balance is affected, adaptations to the exercise or the environment can reduce the risk of falls</td>
<td>• Exercise is beneficial and achievable regardless of a person’s level of disability</td>
</tr>
<tr>
<td>• Exercise recommendations should be tailored to address a person’s needs/capacity, as well as personal preferences</td>
<td>• Referrals to specialists are more essential as disability increases, to assure safety, proper form, and appropriate intensity</td>
<td>• Exercise can be independent (e.g. breathing exercises, arm movements) or facilitated by trained assistants (e.g. stretching, range of motion, transfers)</td>
</tr>
<tr>
<td>• Supervised training generally provides better results than non-supervised training</td>
<td>• Aerobic: heat sensitivity in some patients may require cooling interventions</td>
<td>• Exercise at this level of disability needs to be guided by a specialist, but may be carried out by trained family or caregivers</td>
</tr>
<tr>
<td>• Exercise may temporarily worsen symptoms in patients who are heat-sensitive</td>
<td>• <em>Resistance</em>: daily, 2–3 sets of each stretch, hold 30–60 sec/stretch; modalities might include yoga and stretching exercises</td>
<td><strong>Recommended exercise strategies, EDSS 7.0–7.5</strong> Up to 20 min/day, 3–7 days/week (with each person working to her or his own maximum in order to make gains)—can be accumulated across several shorter sessions, with rest breaks between repetitions and gradual progression in small increments toward the goal:</td>

</table>

**Expert Opinion:**
- At EDSS 7.0–7.5, consider rehabilitation and exercise strategies to remediate deficits in functional mobility: gait training, transfer training, and balance
- Caregiver training, especially at higher EDSS scores, is essential
- Consider the impact of immobility as well as disease progression on mobility status
- Schedule rest breaks to allow for more exercises
- Equipment needs are a major focus

### EDSS 8.0–8.5 (increasing difficulty performing ADLs—confined to wheelchair)

**Key messages**
- Same as for EDSS 7.0–7.5 plus the following:
  - At EDSS 8.0–8.5, consider strategies that promote quality of life/flexibility and reduce morbidity/mortality risks: endurance activities (e.g. arm cycling, lower extremity FES cycling) therapeutic standing, respiratory muscle training

**Recommended exercise strategies, EDSS 8.0–8.5**
- Up to 10–15 min/day, 3–7 days/week with rests between repetitions
- Breathing
  - Same as 7.0–7.5
- Flexibility
  - 1x/day, ≥30–60 seconds, hold/stretch all affected upper and lower extremity joints, with assistance as needed
  - Upper extremities
  - 6x a 3-minute intervals at a target HR (or 70% effort), active range of motion with resistance as able (e.g. arm cycling)
  - 3x/week, 3 sets of 10 repetitions/set or 10 sets of 3 repetitions/set; weights or resistance bands appropriate to ability level
  - Lower extremities
  - 2–3x/day, 1–2 minutes of standing with assistance
  - 3x/week; 30 minutes; standing frame
  - Core
  - 2x/day, 3–5 repetitions of seated isometric abdominal muscle strengthening, holding each repetition 5–6 seconds
  - 1–2 min/day of moving or stationary seated balance, unsupported and supported
  - Every 1–2 hours, posture exercises (pull shoulder blades back/head up straighten back), hold for 10–15 seconds

**Expert Opinion:**
- Same as for EDSS 7.0–7.5

### EDSS 9.0 (inability to perform most ADLs—confined to bed or chair)

**Key messages**
- Same as for EDSS 7.0–7.5 and 8.0–8.5

**Recommended exercise strategies, EDSS 9.0**
- Up to 10 min/day, 3–7 days/week as tolerated with rest as needed
- Breathing
  - Same as 7.0–7.5
- Flexibility
  - Daily passive ROM of all joints with evidence of restriction
  - Active ROM as able
  - FES
  - For ROM to maintain muscle mass/circulation

---

**Table 2. (Continued)**

Table 3. Lifestyle physical activity recommendations and key messages for EDSS 0–9.0.

<table>
<thead>
<tr>
<th>EDSS 0–4.5 (mild impairments)</th>
<th>Recommended lifestyle physical activity strategies</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Key messages</strong></td>
<td>• Options are: selected rather than prescribed, planned or unplanned/spontaneous, and accumulated in one long bout or multiple, short bouts throughout the day.</td>
</tr>
<tr>
<td></td>
<td>• Physical activity is facilitated through behavior change strategies/techniques (e.g. self-monitoring) and environmental stimuli/prompts (e.g. alarms or calendar notes).</td>
</tr>
<tr>
<td></td>
<td>• Physical activity levels can be tracked through self-report (journal) or devices (accelerometry).</td>
</tr>
<tr>
<td></td>
<td>• Options include: 150 minutes per week or 30 minutes 5 days per week; 7,500 steps per day (0.5 standard deviation above the expected for the MS population and a clinically meaningful change); increasing daily steps by 800 per day (smallest MCID); or increasing daily steps by 15% per day (smallest MCID); Godin Leisure-Time Exercise Questionnaire health contribution scores of either 24+ or 14–23 units based on starting point of 14–23 or &lt;14 units, respectively.</td>
</tr>
</tbody>
</table>

**Expert Opinion:**
- Evidence that most individuals with MS and in the general population do not meet recommended levels of physical activity has prompted a shift from exercise training for fitness toward lifestyle physical activity for health and wellness.
- Options include walking, gardening, road cycling, hiking with poles, individual and team sports, and dancing.
- Approaches for changing lifestyle physical activity can be delivered in person or through indirect channels (Internet, phone calls, or newsletters).
- Motion sensors can help monitor activity and serve as motivation.

<table>
<thead>
<tr>
<th>EDSS 5.0–6.5 (increasing mobility impairments)</th>
<th>Participation options</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Key messages</strong></td>
<td>Same as above, plus</td>
</tr>
<tr>
<td>Same as above, plus</td>
<td>Participation options</td>
</tr>
<tr>
<td>• Using the appropriate mobility aid can promote physical activity and safety</td>
<td>Same as above</td>
</tr>
<tr>
<td>• Adapted leisure activities can increase physical activity levels</td>
<td>Participation options</td>
</tr>
<tr>
<td>• Specialists can facilitate greater physical activity levels</td>
<td>Same as above</td>
</tr>
</tbody>
</table>

**Expert Opinion/Clinical Considerations:**
- Inconsistencies may exist when recording step count for people using mobility aids.
- Decline in the amount of physical activity often parallels the person’s reluctance to use a more progressive mobility device.
- Adherence improves with enjoyable activities and ability to demonstrate progress toward goals.
