**Abstract:** A new class of hybrid Lewis acid/Lewis base catalysts has been designed and prepared with an initial objective of promoting stereoselective direct aldol reactions. Several scaffolds were synthesized that contain amine moieties capable of enamine catalysis, connected to heterocyclic metal-chelating sections composed of an oxazole–oxazoline or thiazole–oxazoline. Early screening results have identified oxazole–oxazoline-based systems capable of promoting a highly diastereo- and enantioselective direct aldol reaction of propionaldehyde with 4-nitrobenzaldehyde, when combined with Lewis acids such as zinc triflate.

**Key words:** hybrid catalysis - aldol reaction - organocatalysis - Lewis acids - oxazoline - asymmetric catalysis

The use of small molecule organocatalysts to promote carbon–carbon bond formation is now an established strategy for the preparation of complex organic molecules. The discoveries by Eder and co-workers and Hajos and co-workers that proline can catalyze highly enantioselective intramolecular aldol reactions, as well as the report by List that it can catalyze highly enantioselective intermolecular aldol reactions, led to an explosion of research into the design and utility of organocatalysts. Proline is a simple and elegant example of a bifunctional organocatalyst that serves to activate a ‘donor’ aldehyde or ketone via enamine formation with its amine moiety, for addition to an appropriate acceptor that is activated by the carboxylic acid (Scheme 1, top). There are now many related bifunctional organocatalysts incorporating various hydrogen-bond donors to activate different acceptors, but more rare are reports of hybrid catalysts containing discreet and separate metal Lewis acid/organic Lewis base moieties for carbon–carbon bond formation. Despite the intense study of organocatalysts in recent years, as a class...
their activities continue to be significantly lower than those of enzymes and transition-metal catalysts. An additional challenge (not unique to organocatalysts) is that specific diastereomeric products may be difficult to obtain. A possible solution to some of these shortcomings may lie in the replacement of Brønsted acids or hydrogen-bond donors with chelated Lewis acids (e.g., Scheme 1, bottom). This approach offers the flexibility of using a wide range of Lewis acids, including transition and rare earth metals, as well as the ability to modulate metal and ligand geometries and electronics. A seminal example of such a hybrid Lewis acid/Lewis base catalyst is the ferrocenylphosphine–gold(I) complexes with tethered amines reported by Ito and Hayashi for asymmetric aldol reactions with isocyanoacetate substrates.\(^6\) Other representative examples for carbon–carbon bond formation include reports from the labs of Shibasaki,\(^7\) Kozlowski,\(^8\) Lin,\(^9\) Whiting,\(^10\) Hong,\(^11\) Dixon,\(^12\) and Dong.\(^13\)

**Scheme 1** Design of bifunctional direct aldol catalysts

With an initial interest in identifying direct aldol reaction catalysts that could be useful for the efficient preparation of polypropionate natural product analogues, we have designed a number of hybrid Lewis acid/Lewis base catalysts with the potential to promote various carbon–carbon bond formations. This manuscript discloses our early efforts to identify novel bifunctional catalysts capable of promoting catalytic direct aldol reactions.\(^14\) The combination of amino acid derivatives and Lewis acidic transition metals as catalysts for direct aldol reactions is an approach that has been explored previously,\(^15\) \(^16\) \(^17\) \(^18\) \(^19\) \(^20\) \(^21\) but these catalysts have generally not displayed activities above those of standard organocatalysts, nor have they provided access to unique products. Therefore, we believe that
this strategy is worthy of further investigation, especially since it is an approach that has been effectively used by Nature in type-II aldolases.22

Scheme 2 Synthesis of oxazole–oxazoline precatalysts

Scheme 3 Synthesis of thiazole–oxazoline precatalyst

A significant challenge inherent with multifunctional catalysts is the possibility for self-quenching. It is necessary for the activating moieties to be close enough in space to bring the substrates together, but not so close as to interact negatively with each other. Our initial design (Scheme 1, bottom) utilizes 5-membered heterocycles to act as a spacer between the amine and Lewis acid, while concurrently acting...
as a multidentate ligand to hold the Lewis acid in a favorable orientation. Hybrid catalysts with pyridine-based scaffolds have been reported by Wang and Zhao for cross-aldol reactions with ketone donors.

Our desire for air- and moisture-tolerant catalysts inspired us to design oxazoline-based systems, a well-established ligand for asymmetric synthesis using a variety of Lewis acidic transition metals. The preparation of an oxazole–oxazoline precatalyst is outlined in Scheme 2. N-Boc-1-proline was coupled to l-serine methyl ester with EDC to form dipeptide 1. The dipeptide was reacted with Deoxo-Fluor [bis(2-methoxyethyl)aminosulfur trifluoride] according to a protocol reported by Wipf and Williams to form an intermediate oxazoline, which was treated with DBU and BrCCl₃ and allowed to warm to room temperature to form the oxazole 2. The yield of 2 improved in our hands using an aqueous workup (NaHCO₃ wash) prior to forming the oxazole, rather than using a one-pot protocol. Next, the methyl ester was hydrolyzed and the resulting acid 3 was cleanly coupled with 2-amino-2-methylpropanol to obtain amide 4. This was again cyclized using Deoxo-Fluor to oxazole–oxazoline 5, then the Boc group was removed to provide the desired precatalyst as its HCl salt 6a. The valine-based precatalysts 7 and 8 (Scheme 2) were prepared by a similar strategy (see Supporting Information).

Next, a thiazole analogue of precatalyst 6 was prepared (Scheme 3). Peptide coupling of N-Boc-1-proline and l-threonine methyl ester with EDC gave the desired amide 9. Subsequent Dess–Martin periodinane (DMP) oxidation and treatment with Lawesson’s reagent produced thiazole 11, followed by ester hydrolysis to yield acid 12. Peptide coupling of 12 with 2-amino-2-methylpropanol using EDC led to unsatisfactory yields, so alternatively the mixed anhydride was prepared from isobutyl chloroformate and treated with the amino alcohol, giving amide 13 in reasonable yield. Oxazoline 14 was synthesized using analogous conditions to the oxazole, and finally amine deprotection with TFA and neutralization gave the thiazole–oxazoline precatalyst 15b.
With a collection of precatalysts in hand, we tested them in the direct aldol reaction of propionaldehyde (16a) and 4-nitrobenzaldehyde (17a). Reactions were run with 0.1 mmol of 4-nitrobenzaldehyde (17a) as the limiting reagent, and were subsequently treated with excess NaBH₄ to reduce the aldehyde products and prevent any epimerization or condensation reactions that could complicate analyses. Isomer ratios and reaction yields were determined by chiral normal-phase HPLC (see Supporting Information for details).

* Enantiomeric excess and yield determined by chiral HPLC with 1,2-dichlorobenzene as internal standard. Reaction conditions: 4-nitrobenzaldehyde (0.10 mmol, 0.1 M final concentration), propionaldehyde (0.20 mmol), precatalyst (10 mol%), metal salt (10 mol%), THF, 24 h.

b No reaction observed.
Each precatalyst was tested initially with 15 different metal salts in THF, with select results presented in Table 1. Optimal results were observed with the oxazole–oxazoline catalyst 6b (entries 1–12). A number of common Lewis acids yielded no reaction when combined with 6b (entries 1–5). Counterion effects were observed with some metal salts; for example InCl₃ (entry 6) gave superior yield to In(OTf)₃ (entry 7), and superior enantioselectivities were observed with Zn(OTf)₂ (entry 12) than with ZnBr₂ (entry 11). Decent anti selectivity (77%) and good enantioselectivity (79% ee) was observed with Mg(OTf)₂, but the yield (17%) was low (entry 10). Though our HPLC methods were unable to quantify the amount of unreacted 4-nitrobenzaldehyde precisely, low-yielding reactions corresponded to reactions with high amounts of unreacted 4-nitrobenzaldehyde, which was observed as the 4-nitrobenzyl alcohol after reductive work-up. The alternative precatalysts 7b, 8b, and 15b generally showed decreased yields and enantioselectivities; representative results with Zn(OTf)₂ are provided (entries 13–15). The primary amine precatalyst 7b is the only one described here with any syn selectivity (64% syn, entry 13), though we are currently exploring alternative primary amine based catalysts that may be more effective for syn-aldol reactions. As a benchmark to our results in Table 1, l-proline, previously reported for cross-aldol reactions with aldehydes, gave decent anti selectivity (81%) and enantioselectivity (83% ee) under our screening conditions, but with only 33% yield. No reaction was observed with only Zn(OTf)₂ (entry 17) and very limited reaction was observed with only 6b in THF (entry 18); other control reactions are discussed with Table 2. An initial screen of various additives (acids, bases, Lewis bases, and halide salts) in aldol reactions with benzaldehyde and 4-nitrobenzaldehyde did not yield any improvements in diastereoselectivity, enantioselectivity, or yield with Zn(OTf)₂ or InCl₃ and several different precatalysts; the only exception was the use of certain basic additives such as DBU, which boosted the yield and destroyed all enantioselectivity, likely by promoting a background reaction as well as facilitating the retroaldol reaction to equilibrate the isomeric mixture of products.

^a Enantiomeric excess and yield was determined by chiral HPLC with 1,2-dichlorobenzene as internal standard. Reaction conditions: 4-nitrobenzaldehyde (0.10 mmol, 0.1 M final concentration), propionaldehyde (0.20 mmol), precatalyst (10 mol%), metal salt (10 mol%), 24 h, unless otherwise noted. ^b Isolated yield. Reactions were run for 48 h with 4-nitrobenzaldehyde (1.0 mmol), at a final concentration of 0.25 M. See Supporting Information for details.
More promising results were observed in investigations of solvent effects and water concentrations (Table 2). In particular, water had a drastic effect on both diastereoselectivity and enantioselectivity. The use of MeCN/H₂O (1:1) gave a significant improvement in yield versus just MeCN, but completely abrogated the enantioselectivity for the anti product (entries 5 vs. 6). Alternatively, decreasing the amount of water by an order of magnitude (entry 7) gave excellent enantioselectivity (92% ee for the anti product) with the catalyst generated from 6b and Zn(OTf)₂, with moderate yield (54%). Decreasing the amount of water decreased the diastereoselectivity somewhat, and decreased the enantioselectivity of the anti product significantly (entries 8–10). The use of MeCN/H₂O (9:1) also gave excellent results with 6b and InCl₃ (90% anti selective, 93% ee, 52% isolated yield, entry 11).

a Enantiomeric excess and yield was determined by chiral HPLC with 1,2-dichlorobenzene as internal standard. Reaction conditions: acceptor (0.4 mmol), donor (0.8 mmol), 6b (10 mol%), Zn(OTf)₂ (10 mol%), MeCN/H₂O (9:1), 20 °C, 24 h (with 17a) or 70 °C, 48 h (with 17b and 17c), unless otherwise noted. Reductive work-ups were performed for reactions with aldehyde donors (16a, 16b).

b Isolated yield after 48 h with 4-nitrobenzaldehyde (1.0 mmol) and propionaldehyde (2.0 mmol), at a final concentration of 0.25 M. See Supporting Information for details.

c No reaction observed.

Data from several control experiments are also included in Table 2. To demonstrate that optimal results are observed with a bifunctional
catalyst over dual catalysis using a discrete organocatalyst and Lewis acid catalyst, we studied the use of several catalyst combinations for the addition of propionaldehyde (16a) to 4-nitrobenzaldehyde (17a) under our optimal conditions. First, the Boc-protected precursor 5 to the bifunctional precatalyst 6b gave only trace reaction on its own (entry 13), and also trace reaction when combined with Zn(OTf)$_2$ (entry 14); at most compound 5 could act as a ligand for Zn(OTf)$_2$. Racemic 2-phenylpyrrolidine was used as a surrogate for the strictly Lewis or Brønsted basic aspects of our hybrid catalyst; it gave a fairly significant background reaction (30% yield, entry 15), but this was attenuated when it was combined with Zn(OTf)$_2$ (11% yield, entry 16). With the combination of 5 and Zn(OTf)$_2$ (10 mol% each) plus 2-phenylpyrrolidine (entry 17), no improvement in yield is obtained compared to simply 2-phenylpyrrolidine, which suggests that a dual catalysis mechanism may not be operative, and 6b and Zn(OTf)$_2$ (entry 7) may indeed act as a hybrid catalyst.
Figure 1 $^1$H NMR spectra in CD$_3$CN of 6b (top) and 6b + InCl$_3$ (1 equiv) (bottom)
We selected Zn(OTf)₂ over InCl₃ for further study because of the possibility for InCl₃ to promote a background reaction via a non-hybrid catalyst pathway; we had observed that pyrrolidine and InCl₃ (10 mol% each) promoted the addition of propionaldehyde (16a) to 4-nitrobenzaldehyde (17a) in THF at room temperature in 48% yield, though no reaction was observed with benzaldehyde under these circumstances. The combination of 6b and Zn(OTf)₂ was tested with several alternative donor and acceptor combinations (Table 3). A sluggish reaction of propionaldehyde (16a) with 4-chlorobenzaldehyde (17b) (entry 2) was observed, and no reaction was observed between benzaldehyde (17c) and several different donors. A low-yielding reaction was observed between cyclohexanone (16c) and 4-nitrobenzaldehyde (17a) (entry 7).

In order to potentially shed some light on the nature of our active catalysts and the factors that may govern their reactivities, we performed some simple NMR studies examining the interactions between precatalyst 6b and several metal salts giving catalysts with good activity, including Zn(OTf)₂ and InCl₃. With zinc salts, highly broad peaks were observed, suggesting that a variety of coordination states are present that interchange on the NMR timescale. Spectra with InCl₃ were more directly informative. The combination of 6b and 1 equivalent of InCl₃ led to downfield shifts in all of the signals in the spectrum of 6b (Figure 1), suggesting that the metal may coordinate to both the oxazole–oxazoline as well as the pyrrolidine moieties. Interestingly, the diastereotopic oxazoline methylene and methyl protons become separate signals only after metal coordination. The substantial shift of the protons at both the 2- and the 5-positions of the pyrrolidine (labeled a and d in the Figure 1) after addition of InCl₃ is additional evidence that coordination to the pyrrolidine nitrogen is occurring, and 6b is certainly capable of bridging two metal centers. We hypothesize that the lack of obvious improvement in catalytic activity of our and other bifunctional catalysts versus simple amine-based organocatalysts may be due to the fact that the amine is at least partially tied up by the metal, even if it may be in a reversible manner. When excess 6b (up to 2.5 equiv) is mixed with InCl₃, there is no evidence for the combination of free ligand in solution together with a ligand–metal complex. This suggests a dynamic binding process where the ligand is coming on and off the metal rapidly, giving a spectrum that represents the average of each ligand species. There is
also no change in these spectra upon cooling to –20 °C, which is evidence that any exchange process is very rapid on the NMR timescale. Our current efforts are directed towards the synthesis of alternative systems that will be less prone to potential intermolecular coordination of catalyst Lewis acid/Lewis base functionality.

In conclusion, we have designed and prepared several heterocyclic scaffolds capable of supporting bifunctional Lewis acid/Lewis base catalysis. Proof of concept was obtained for the bifunctional catalysis of a direct aldehyde cross-aldol reaction using a proline-derived oxazole–oxazoline scaffold 6b with a number of Lewis acids, though the substrate scope is presently limited. Additional investigations with related scaffolds are underway to identify efficient catalysts capable of promoting carbon–carbon bond formations between aldehyde/ketone donors and less activated acceptors, which continues to be a general challenge in this field.

All reagents and solvents were purchased from commercial vendors and used as received. NMR spectra were recorded on Varian 300 MHz or 400 MHz spectrometers as indicated relative to TMS, CDCl₃ solvent, or DMSO-d₆ (¹H δ = 0, ¹³C δ = 77.16, or ¹³C δ = 39.5, respectively). Unless otherwise indicated, NMR data were collected at 25 °C. Flash chromatography was performed using Biotage SNAP cartridges filled with 40–60 μm silica gel, or C18 reverse phase columns (Biotage® SNAP Ultra C18 or Isco RediSep® Gold C18Aq) on Biotage Isolera systems, with photodiode array UV detectors. Analytical TLC was performed on Agela Technologies 0.25-mm glass plates with 0.25-mm silica gel. Visualization was accomplished with UV light (254 nm) and aq KMnO₄ stain followed by heating, unless otherwise noted. Tandem liquid chromatography/mass spectrometry (LC-MS) was performed on a Shimadzu LCMS-2020 with autosampler, photodiode array detector, and single-quadrupole MS with ESI and APCI dual ionization, using a Peak Scientific nitrogen generator. Unless otherwise noted, a standard LC-MS method was used to analyze reactions and reaction products: Phenomenex Gemini C18 column (100 × 4.6 mm, 3 μm particle size, 110 Å pore size); column temperature 40 °C; 5 μL of sample in MeOH at a nominal concentration of 1 mg/mL was injected, and peaks were eluted with a gradient of 25–95% MeOH/H₂O (both with 0.1% formic acid) over 5 min, then 95% MeOH/H₂O for 2 min. Purity was measured by UV
absorbance at 210 or 254 nm. HRMS were obtained at the University of Wisconsin-Milwaukee Mass Spectrometry Laboratory with a Shimadzu LCMS-IT-TOF with ESI and APCI ionization. Gas chromatography/mass spectrometry (GC-MS) was performed with Agilent Technologies 6850 GC with 5973 MS detector, and Agilent HP-5S or Phenomenex Zebron ZB-5MSi Guardian columns (30 m, 0.25 mm ID, 0.25 μm film thickness). IR spectra were obtained as a thin film on NaCl or KBr plates using a Thermo Scientific Nicolet iS5 spectrophotometer. Optical rotations were measured with a Perkin Elmer 341 polarimeter at 589 nm, with a 10-mL cell with 10-cm path length. Specific rotations are reported as follows: \([\alpha]_D^{\text{o}} \, ^\circ \text{C} \, (c = g/100 \text{ mL}, \text{solvent}).\)

Spectral data for Boc-protected proline derivatives may be complicated by rotamers.

**tert-Butyl (2S)-2-\{[(2S)-3-Hydroxy-1-methoxy-1-oxopropan-2-yl]carbamoyl\}pyrrolidine-1-carboxylate (1)**

Methyl 2-[(2S)-1-(tert-Butoxycarbonyl)pyrrolidin-2-yl]oxazole-4-carboxylate (2)

[CAS Reg. No. 955401-52-2]

Dipeptide 1 (3.42 g, 10.8 mmol) was added to a 250-mL flask with stir bar and sealed under N₂, then THF (120 mL) was added, and the solution was cooled to −20 °C. Deoxo-Fluor (2.12 mL, 11.9 mmol) was added via syringe, and the mixture was stirred for 45 min at −20 °C. The reaction was then quenched with sat. aq NaHCO₃ (~30 mL). The organic portion was dried (Na₂SO₄), filtered, and concentrated and dried under high vacuum. The crude material was redissolved in THF (120 mL) and cooled to 0 °C in an ice bath. BrCCl₃ (3.94 mL, 40.0 mmol) was added via syringe, followed by DBU (5.16 mL, 40.0 mmol), which was added dropwise over ~5 min. The mixture was removed from the ice bath and allowed to warm to r.t. while stirring for 17 h. Water (100 mL) was added to the solution, then the mixture was extracted with EtOAc (3 ×) in a separatory funnel. The combined organics were dried (Na₂SO₄), filtered, and concentrated to a dark brown oil. The crude was purified by flash chromatography (100 g silica gel cartridge; 0–100% EtOAc/hexanes gradient) to yield the product (2.51 g, 78%) as a white solid. This compound has been previously reported and characterized.³³

¹H NMR (300 MHz, CDCl₃): δ = 1.29 (Boc peak, rotamer 1), 1.44 (Boc peak, rotamer 2) (9 H), 1.86–2.01 (m, 1 H), 2.03–2.20 (comp, 2 H), 2.24–2.45 (m, 1 H), 3.44–3.68 (comp, 2 H), 3.84–3.98 (comp, 3 H), 4.89–5.07 (comp, 1 H), 8.18 (s, 1 H).

2-[(2S)-1-(tert-Butoxycarbonyl)pyrrolidin-2-yl]oxazole-4-carboxylic Acid (3)

[CAS Reg. No. 1511857-57-0]

Ester 2 (2.48 g, 8.37 mmol) was added to a 50-mL flask with stir bar along with THF (25 mL) and water (8 mL). LiOH (261 mg, 17.6 mmol) was added and the flask was stirred for 24 h, after which time TLC analysis (10% MeOH/CH₂Cl₂) indicated that the reaction was complete. The mixture was diluted with CH₂Cl₂ (~75 mL) and water (~75 mL), then the pH was adjusted to 4 with 2 M aq HCl. The layers
were separated and the aqueous phase was re-extracted with CH$_2$Cl$_2$ (2 × 50 mL). The combined organics were then dried (Na$_2$SO$_4$), filtered, and concentrated to yield the product (1.23 g, 94%) as an off-white foam. This compound has been previously reported and characterized.\textsuperscript{34}

IR (thin film): 3435, 2978, 2537, 1685, 1585, 1406, 1250, 1611, 1113, 982 cm$^{-1}$.

**tert-Butyl (2S)-2-{{(2S)-3-Hydroxy-1-methoxy-1-oxobutan-2-yl}carbamoyl}pyrrolidine-1-carboxylate (9)**

[CAS Reg. No. 955401-36-2]

N-Boc-L-proline (3.75 g, 17.4 mmol), L-threonine methyl ester HCl (2.96 g, 17.4 mmol), and HOBt (2.94 g, 19.2 mmol) were added to a 250-mL round-bottom flask equipped with a magnetic stir bar. CH$_2$Cl$_2$ (100 mL) was then added followed by DIPEA (6.76 g, 52.3 mmol). The mixture was stirred for 5 min then EDC·HCl (3.67 g, 19.2 mmol) was added. The flask was sealed with a septum and stirred at r.t. for 24 h, after which time the starting material had been consumed (LC-MS). The mixture was diluted with CH$_2$Cl$_2$ (200 mL), and the organic layer was separated and washed with 0.1 M HCl, deionized water, sat. NaHCO$_3$, and finally brine. The combined organics were dried (Na$_2$SO$_4$) and concentrated under vacuum to afford a pale yellow oil. The crude oil was taken up in minimal CH$_2$Cl$_2$ and purified by flash chromatography (100 g silica gel column, 0–11% MeOH/CH$_2$Cl$_2$ gradient) to yield 9 (4.1 g, 58%) as a clear colorless oil. The $^1$H NMR data obtained were in agreement with that reported in the literature.$^{35}$

$^1$H NMR (400 MHz, CDCl$_3$): $\delta$ = 1.22 (d, $J = 1.0$ Hz, 3 H), 1.47 (s, 9 H), 1.84–1.98 (m, 2 H), 2.10–2.49 (m, 2 H), 2.76 (br, 1 H), 3.30–3.58 (m, 2 H), 3.77 (s, 3 H), 4.27–4.33 (m, 1 H), 4.58 (dd, $J = 9.0$, 2.86 Hz, 1 H).

**Methyl [(2S)-1-(tert-Butoxycarbonyl)pyrrolidin-2-yl]-5-methyl-thiazole-4-carboxylate (11)**

[CAS Reg. No. 347191-33-7]
Alcohol 9 (3.60 g, 10.9 mmol) was added to a 250-mL round-bottom flask containing CH₂Cl₂ (150 mL) and DMP (5.08 g, 12.0 mmol). The mixture was stirred at r.t. for 1 h before water was added (0.816 g, 45.3 mmol), then stirred for a further 1 h before the consumption of the starting material was observed (LC-MS). The crude was filtered through basic alumina to remove precipitated salts and concentrated to afford 10 (2.20 g, 61%) as a colorless oil. The product was taken directly on to the next step without further purification.

Keto ester 10 (2.50 g, 7.61 mmol) was taken up in dry THF (40 mL). Lawesson’s reagent (6.16 g, 15.2 mmol) was added and the flask was fitted with a condenser and sealed with a rubber septum. The apparatus was purged with N₂ and placed under positive N₂ pressure then refluxed for 24 h, after which time TLC indicated the consumption of starting material. The mixture was cooled to r.t. and diluted with CH₂Cl₂ (100 mL), then the organic layer was washed with sat. NaHCO₃, water, and brine, dried (Na₂SO₄), and concentrated. The crude was purified via flash chromatography (50 g silica gel, 0–78% EtOAc/hexanes gradient) to yield 11 (1.34 g, 54%) as an orange oil. The ¹H NMR data obtained were in agreement with that reported in the literature.³⁶

¹H NMR (300 MHz, CDCl₃): δ = 1.31 (s, 6 H), 1.47 (s, 3 H), 1.92 (br, 2 H), 2.13–2.42 (m, 2 H), 2.75 (s, 3 H), 3.29–3.68 (m, 2 H), 3.93 (s, 3 H), 5.08–5.21 (m, 1 H).

2-[(2S)-1-(tert-Butoxycarbonyl)pyrrolidin-2-yl]-5-methylthiazole-4-carboxylic Acid (12)

Thiazole 11 (1.34 g, 4.00 mmol) was added to a 500-mL round-bottom flask followed by MeOH (150 mL) and H₂O (40 mL), along with NaOH pellets (0.82 g, 20.5 mmol). The mixture was stirred at reflux for 48 h, after which time the starting material had been consumed (LC-MS). The mixture was brought to neutral pH using 2 M HCl, and the solvent was removed to afford an oily orange solid. Deionized water was added, and the solution was extracted with CH₂Cl₂ (3 ×). The organic layers were combined, washed with brine, dried (Na₂SO₄), and concentrated to afford an orange foam. The crude material was taken up into CH₂Cl₂ and purified via flash chromatography (50 g silica gel, 0–78% EtOAc/hexanes gradient) to yield 12 (0.84 g, 54%) as an orange oil.
gel column, 0–100% EtOAc/hexanes gradient) to yield 12 (0.97 g, 75%) as a tan oil; $R_f = 0.31$ (EtOAc/hexanes, 50:50).

$[\alpha]_D^{25} = -97$ (0.156, CH$_2$Cl$_2$).

IR (thin film): 3411, 2976, 1700, 1394, 1166, 729 cm$^{-1}$

$^1$H NMR (300 MHz, CDCl$_3$): $\delta = 1.31$ (rotamer 1), 1.49 (rotamer 2) (9 H), 1.96 (br, 2 H), 2.29 (br, 2 H), 2.78 (br, 3 H), 3.57 (br, 2 H), 5.09 (br, 1 H).

$^{13}$C NMR is complicated due to rotamers.

$^{13}$C NMR (101 MHz, CDCl$_3$): $\delta = 13.2, 14.2, 21.0, 23.2, 24.0, 28.3, 28.4, 32.6, 34.0, 46.6, 47.0, 58.7, 59.3, 80.6, 128.5, 131.7, 141.7, 145.5, 154.2, 163.9, 164.4, 170.6, 171.3, 171.6.$

HRMS (ESI$^+$): $m/z$ [M + H]$^+$ calcd for C$_{14}$H$_{21}$N$_2$O$_4$S: 313.1217; found: 313.1210.

**tert-Butyl (2S)-2-{4-[2-Hydroxy-2-methylpropan-2-yl]carbamoyl]-5-methylthiazol-2-yl}pyrrolidine-1-carboxylate (13)**

Carboxylic acid 12 (1.01 g, 3.22 mmol) was added to a 100-mL round-bottom flask with CH$_2$Cl$_2$ (20 mL), followed by DIPEA (0.833 g, 6.45 mmol). Isobutyl chloroformate (0.484 g, 3.55 mmol) was added dropwise then the mixture was stirred at r.t. After 2 h, consumption of the carboxylic acid and the formation of the mixed anhydride were observed (LC-MS). During the mixed anhydride formation, 2-amino-2-methylpropanol (0.486 g, 3.87 mmol) and DIPEA (0.417 g, 3.22 mmol) were stirred at r.t. in CH$_2$Cl$_2$ (20 mL) in a separate flask. After the formation of the mixed anhydride was complete, the 2-amino-2-methylpropanol/DIPEA mixture was added and the mixture was stirred overnight, after which time LC-MS indicated complete consumption of the mixed anhydride. The mixture was washed with 0.1 M HCl, sat. NaHCO$_3$, and brine. Acid and base washes were each back extracted with EtOAc (2 × 10 mL). The combined organic layers were dried (Na$_2$SO$_4$) and concentrated to give a yellow oil, then dissolved in CH$_2$Cl$_2$ and purified via flash chromatography (25 g silica gel column,
0–100% EtOAc/hexanes gradient) to yield 13 (0.73 g, 59%); 
$R_f = 0.50$ (EtOAc/hexanes, 50:50).

$[\alpha]_D^{25} = -52$ (0.217, CH$_2$Cl$_2$).

IR (thin film): 3350, 2975, 2250, 1690, 1400, 1050, 725 cm$^{-1}$

$^1$H NMR (400 MHz, CDCl$_3$): $\delta = 1.33$ (s, 6 H), 1.36 (rotamer 1), 1.45 (rotamer 2) (9 H), 1.94 (br, 2 H), 2.14 (br, 1 H), 2.24 (br $s$, 1 H), 2.65–2.78 (m, 3 H), 3.41 (m, $J = 9.2, 8.1$ Hz, 1 H), 3.54 (br, 1 H), 3.61–3.73 (m, 2 H), 4.87–5.34 (m, 1 H), 7.51 (s, 1 H).

Carbon NMR is complicated due to rotamers.

$^{13}$C NMR (101 MHz, CDCl$_3$): $\delta = 12.8, 14.2, 23.1, 23.9, 24.8, 28.4, 32.7, 33.8, 46.4, 46.9, 56.0, 58.8, 59.0, 70.9, 80.2, 140.6, 142.0, 142.1, 154.1, 154.6, 163.6, 169.4, 169.8, 171.1.$

**tert-Butyl (2S)-2-[4-(4,4-Dimethyl-4,5-dihydrooxazol-2-yl)-5-methylthiazol-2-yl]pyrrolidine-1-carboxylate (14)**

Amino alcohol 13 (0.730 g, 1.90 mmol) was added to a 15-mL round-bottom flask. The flask was sealed under N$_2$ and dry THF (5 mL) was added and cooled to $-20$ °C. Deoxo-fluor (0.463 g, 2.09 mmol) was added dropwise over 5 min. The mixture was stirred at $-20$ °C for 1 h, after which time LC-MS indicated the consumption of the starting material. The mixture was allowed to warm to 5 °C and then quenched with sat. aq NaHCO$_3$ (5 mL). The aqueous layer was extracted with CH$_2$Cl$_2$ (3 × 5 mL), and the combined organic layers were dried (Na$_2$SO$_4$) and concentrated to give an orange oil. The crude oil was dissolved in CH$_2$Cl$_2$ and purified via flash chromatography (10 g silica gel column, 0–100% EtOAc/hexanes gradient) to yield 14 (0.56 g, 80%) as a pale yellow oil; $R_f = 0.80$ (EtOAc/hexanes, 50:50).

$[\alpha]_D^{25} = -63$ (0.270, CH$_2$Cl$_2$).

IR (thin film): 2975, 1690, 1375, 1150 cm$^{-1}$
1H NMR (400 MHz, CDCl3): δ = 1.23 (s, 6 H), 1.26 (rotamer 1), 1.36 (rotamer 2) (9 H), 1.67–1.90 (m, 2 H), 1.99–2.29 (m, 2 H), 2.58 (br, 2 H), 3.24–3.40 (m, 1 H), 3.42 (br, 1 H), 3.98 (br, 2 H), 5.01 (br, 1 H).

13C NMR is complicated due to rotamers.

13C NMR (101 MHz, CDCl3): δ = 12.9, 22.9, 23.7, 28.2, 28.3, 28.4, 32.8, 34.1, 43.3, 46.5, 46.9, 59.0, 59.4, 67.5, 71.3, 78.7, 80.1, 138.4, 139.2, 154.1, 157.9, 172.2.

4-(4,4-Dimethyl-4,5-dihydrooxazol-2-yl)-5-methyl-2-[(2S)-pyrrolidin-2-yl]thiazole (15b)

Compound 14 (0.278 g, 0.761 mmol) was placed in a 4-mL vial followed by TFA (0.173 g, 1.52 mmol) and was allowed to stir overnight at r.t.. The mixture was diluted with water (2 mL), and the pH was brought to 11 using 7.4 M aq NH4OH. The aqueous layers were extracted with EtOAc (3 x), dried (Na2SO4), and concentrated to afford an orange oil. The crude oil was taken up into CH2Cl2 and purified via flash chromatography (5 g silica gel column). The column was flushed with 5 column volumes of EtOAc, then the desired product was eluted with MeOH and concentrated to yield the product (0.124 g, 61%) as a yellow oil; Rf = 0.40 (5% MeOH/CH2Cl2).

[a]D 25 –32 (0.165, CH2Cl2).

IR (thin film): 3300, 2980, 2210, 1650, 725 cm\(^{-1}\).

1. Author contributions

Dennis Wiedenhoeft: Assisted with catalyst design; designed, investigated, and optimized precatalyst syntheses; characterized products; screened reactions; analyzed data; designed experiments; wrote supporting information; supervised research.

Adam Benoit: Assisted with catalyst design; designed, investigated, and optimized precatalyst syntheses; characterized products; developed HPLC methods; screened reactions; analyzed data; designed experiments; wrote supporting information; edited the manuscript; supervised research.

Yibiao Wu: Resynthesized precatalysts; screened reactions; characterized products.

Jacob Porter: Investigated precatalyst synthetic routes; prepared precatalysts; characterized products; screened reactions; performed NMR studies.

Rajdeep Virdi: Investigated precatalyst synthetic routes; prepared precatalysts; characterized products.

Alaa Shanaa: Screened reactions.
2. General reaction screening protocol and HPLC data

Stock solutions of precatalyst (0.02 M), 4-nitrobenzaldehyde (0.40 M), and propionaldehyde (0.80 M) were prepared. All precatalysts were used as free bases (or zwitterions) by neutralizing HCl salts with aqueous ammonium hydroxide and extracting with DCM prior to use.

1) Metal salts (0.01 mmol) were weighed into separate 1.5 mL HPLC vials.

2) If solid additives were included, they were added to the vials at this time.

3) Precatalyst solutions (500 µL of 0.02 M stock solution, 0.01 mmol) were added to each vial.

4) If additive solutions were included, they were added to the vials next.

5) 4-Nitrobenzaldehyde solution (250 µL of 0.40 M solution, 0.1 mmol), was added to each vial.

6) Propionaldehyde (250 µL of 0.80 M solution, 0.2 mmol) was added to each vial.

After addition of all reagents, the vials were capped (PTFE septa) and placed in a cardboard vial box attached to a vortex shaker. Vials were shaken for 24 hours on the lowest speed to avoid leakage from the vials. 9 mL glass test tubes were labeled to correspond to each of the reaction vials and sodium borohydride (~75 mg, 2 mmol, 20 eq.) was added to each tube and cooled on ice. 4:1 DCM:MeOH (1 mL) was added, then the reaction solutions were pipetted dropwise (over ~30 s) to the test tubes. The tubes were removed the ice bath and warmed to room temperature over thirty minutes, with periodic mixing. Saturated aqueous ammonium chloride solution (1 mL) was then added via pipet dropwise (~1 min.) to each tube to quench the reduction reaction, followed by 1 M aqueous HCl (1 mL) added via pipet dropwise (~1 min.) to further neutralize the solutions and to help dissolve solid precipitates. DCM (~1 mL) was added to each tube to resolve the phases. The organic phases were separated to fresh 9 mL tubes, then the remaining solutions were extracted with additional DCM (2 x 2 mL). The combined organic solutions were concentrated via Speedvac (initially at 400 torr with low heating, then 25 torr). A stock solution
of LC-MS grade isopropanol with 5 mg/mL of o-dichlorobenzene as an internal standard was made. Each crude sample was dissolved in 1 mL of this stock solution and filtered through a 0.22 micron nylon syringe filter into a 1.5 mL HPLC vial. The samples were analyzed by HPLC using 5 μL injections and 13:87 IPA:hexane isocratic method (1 mL/min.) for 20 min., with a Phenomenex Lux 5 μm Cellulose-2 column (250 x 4.6 mm) and UV detection at λ = 254 nm. Representative retention times: 3.3 min: o-dichlorobenzene; 9.3 min: benzyl alcohol; 10.7 min., syn enantiomer 1; 12.0 min., syn enantiomer 2; 14.5 min., anti enantiomer 1; 15.6 min., anti enantiomer 2.

3. Representative aldol protocol with 6b

(Table 2, entries 7 and 11)

The precatalyst hydrochloride salt 6a (0.264 g, 0.971 mmol) was added to a 2 dram reaction vial followed by THF (2.5 mL) and conc. ammonium hydroxide (7.44 M, 0.65 mL, 4.84 mmol). The solution was stirred for 10 min. before being diluted with DCM (5.0 mL) and deionized water (3.0 mL). The aqueous layer was separated and re-extracted with DCM (5 mL). The combined organic layers were washed with brine, dried over sodium sulfate, and condensed to afford the neutral precatalyst 6b as a yellow oil which was used without purification (0.144 g, 64%).

Metal salt (10 mol%) was added to a 2 dram reaction vial followed by 6b (10 mol%) added as a solution in 9:1 MeCN/H₂O (2.5 mL). After addition of 6b, an additional 2.5 mL 9:1 MeCN/H₂O was added followed by 4-nitrobenzaldehyde (0.150 g, 1.00 mmol) as a solid. Lastly, propionaldehyde (0.36 mL, 5.0 mmol) was added via syringe, and reactions were stirred at room temperature for 48 hours. The reactions were quenched by pipetting them into a solution of sodium borohydride (0.19 g, 5.0 mmol) in 25% MeOH in DCM (5 mL) in test tubes cooled to 0°C. After 5 min. the reactions were brought to room temperature and allowed to react for an additional 30 min. Lastly, saturated aqueous ammonium chloride (5 mL) was added and the reactions quenched for 20 min. before being diluted with DCM (5 mL). The organic layers were separated and the aqueous layers were re-extracted DCM (5 mL). The combined organic layers were concentrated under reduced pressure to give dark yellow oils. The crude materials were dissolved in minimal DCM and loaded onto a 10 g SiO₂ column and purified via a 0 to 75% MTBE : hexanes gradient to yield the desired products 18aa (isomeric mixtures) as pale yellow oils: Zn(OTf)₂ (0.113 g, 54%); InCl₃ (0.108 g, 52%).
Aldol product 18aa (Table 2, entry 7: Zn(OTf)$_2$)
Aldol product 18aa (Table 2, entry 11: \(\text{InCl}_3\))
Standard HPLC chromatogram (isomeric mixture of 18aa plus 1,2-dichlorobenzene (vide infra))

HPLC chromatogram from aldol reaction with 10 mol% 6b + InCl₃ (Table 2, entry 11):
4. Synthetic protocols for synthesis of precatalysts 7 and 8

\[ \text{SI-1} \quad \text{SI-2} \quad \xrightarrow{\text{EDC, HOBr, (i-Pr)\textsubscript{2}NEt, DCM}} \quad \text{SI-3, 77\%} \]

\[ \text{SI-4a, R=H, 79\%} \quad \text{SI-4b, R=CH}_3 \]

\[ \text{NI-Methylation of the carbamate SI-4a} \]

\[ \text{SI-4a} \quad \xrightarrow{\text{CH}_3, \text{NaH, THF, rt}} \quad \text{SI-4b, 71\%} \]

\[ \text{Methyl (2S)-2-\{(2S)-2-\{(\text{tert-butoxy)carbonyl})amino\}-3\text{-methylbutanamido\}}-3\text{-hydroxypropanoate (SI-3)} \]
N-Boc-L-valine **SI-1** (5.80 g, 26.7 mmol), L-serine methyl ester **SI-2** (4.36 g, 28.0 mmol) and HOBt (5.32 g, 34.7 mmol) were added to a 500 mL round bottom flask with stir bar and dissolved in DCM (250 mL). DIPEA (11.0 mL, 64.1 mmol) was then added by syringe, followed by EDC-HCl (6.65 g, 34.7 mmol). The reaction was stirred at room temperature for 48 h, then the reaction was transferred to a separatory funnel and washed with water (~125 mL), 1M HCl (~125 mL), then saturated sodium bicarbonate (~125 mL). The organic portion was dried with sodium sulfate, filtered, and concentrated to a white solid. The crude compound was dissolved in DCM (~10 mL) and purified by flash chromatography (100 g SiO<sub>2</sub> cartridge; 0 to 10% MeOH/DCM gradient) to yield the title compound as a white solid (6.5 g, 77%). This compound has been previously reported and characterized (CAS# 71017-98-6).

**SI-4a**

Methyl 2-[(1S)-1-[[[\(\text{tert-butoxy}\text{ carbonyl}]\text{amino}] -2-methylpropyl]-1,3-oxazole-4-carboxylate (SI-4a)

Dipeptide **SI-3** (6.50 g, 20.5 mmol) was added to a 500 mL flask with stir bar and sealed under nitrogen, then DCM (200 mL) was added, and the solution was cooled to -20 °C. Deoxo-Fluor (4.14 mL, 22.5 mmol) was added via syringe, and the reactions was stirred for 45 min. at -20 °C. The reaction was then quenched with saturated aqueous sodium bicarbonate (~70 mL). The organic portion was dried with sodium sulfate, filtered, and concentrated and dried under hvacuum. The crude material was redissolved in DCM (200 mL) and cooled to 0 °C in an ice bath. Bromotrichloromethane (7.44 mL, 75.5 mmol) was added via syringe, followed by DBU (9.75 mL, 75.5 mmol), which was added dropwise over ~5 min. The reaction was removed from the ice bath and allowed to warm to room temperature while stirring overnight. Water (200 mL) was added to the solution, then the mixture was extracted with EtOAc (x 3) in a separatory funnel. The combined organics were dried with sodium sulfate, filtered, and concentrated to a dark brown oil. The crude was purified by flash chromatography (100 g SiO<sub>2</sub> cartridge; 0 to 100% EtOAc/hexanes gradient) to yield the title compound as a white solid (6.09 g, 79%). This compound has been previously reported and characterized (CAS# 158068-97-4).

**SI-4a**

\[\text{NHBoc} \]

\[\text{O} \]

\[\text{O} \]

\[\text{SI-4a} \]

1H NMR (300 MHz, CDCl<sub>3</sub>): \(\delta = 0.94 - 1.03 \text{ (m, 6 H)}\), 1.44 (s, 9 H), 1.67 (s, 1 H), 2.01 - 2.20 (m, 1 H), 3.02 (t, \(J=6.1 \text{ Hz}\), 1 H), 3.80 (s, 3 H), 3.82 - 3.91 (m, 1 H), 3.96 (s, 2 H), 4.67 (dt, \(J=7.3, 3.5 \text{ Hz}\), 1 H), 5.10 (d, \(J=8.3 \text{ Hz}\), 1 H), 6.82 (d, \(J=8.0 \text{ Hz}\), 1 H).

1H NMR (300 MHz, CDCl<sub>3</sub>) \(\delta = 0.87 - 0.98 \text{ (m, 6 H)}\), 1.44 (s, 9 H), 2.10 - 2.29 (m, 1 H), 3.92 (s, 3 H), 4.74 - 4.88 (m, 1 H), 5.28 (d, \(J=7.2 \text{ Hz}\), 1 H), 8.19 (s, 1 H).
Methyl 2-[(1S)-1-[(tert-butoxy)carbonyl](methyl)amino]-2-methylpropyl]-1,3-oxazole-4-carboxylate (SI-4b)

Ester SI-4a (2.63 g, 8.82 mmol) was placed in an oven dried 250 mL flask and sealed under nitrogen. Iodomethane (0.58 mL, 9.26 mmol) was added, followed by THF (75 mL). NaH (60% dispersion on paraffin oil, 0.529 g, 13.2 mmol) was added and allowed to react under nitrogen at room temperature overnight. The solution was diluted with DCM (100 mL) and washed with water. The aqueous portion was back extracted with two additional portions of DCM. The combined organics were concentrated and redissolved in DCM (~10 mL), then purified by flash chromatography (100 g SiO$_2$ cartridge; 0 to 100% EtOAc/hexanes gradient) to yield the title compound as a dark yellow oil (1.94 g, 71%). This compound has been previously reported and characterized (CAS# 137008-30-0).

$^1$H NMR (300 MHz, CDCl$_3$) $\delta$ ppm 0.89 - 1.00 (d, 6 H), 1.47 (s, 9 H), 2.50 (dq, $J$=17.7, 6.6 Hz, 1 H), 2.77 (s, 3 H), 3.92 (s, 3 H), 4.83 - 5.23 (dd, 1 H), 8.21 (s, 1 H).

2-[(1S)-1-[(tert-butoxy)carbonyl]amino]-2-methylpropyl]-1,3-oxazole-4-carboxylic acid (SI-5a)

Ester SI-4a (4.50 g, 15.1 mmol) was added to a 250 mL flask with stir bar along with THF (50 mL) and water (15 mL). LiOH (759 mg, 31.7 mmol) was added and the reaction was stirred for 24 h, after which time TLC analysis (10% MeOH/DCM) indicated that the reaction was complete. The reaction was diluted with DCM (~75 mL) and water (~50 mL), then the pH was adjusted to 4 with 2 M aq. HCl. The layers were separated and the aqueous phase was re-extracted with DCM (2 x 50 mL). The combined organics were then dried with sodium sulfate, filtered, and concentrated to yield the title compound as a white solid (4.03 g, 94%). This compound has been previously reported and characterized (CAS# 220717-54-4).

$^1$H NMR (300 MHz, CDCl$_3$): $\delta$ = 0.95 (dd, $J$=13.5, 6.7 Hz, 6 H), 1.42 (s, 9 H), 1.86 (dt, $J$=6.8, 3.2 Hz, 1 H), 2.17 - 2.27 (m, 1 H), 3.76 (s, 1 H), 4.83 (dd, $J$=9.7, 6.2 Hz, 1 H), 5.92 (br, 1 H), 8.29 (s, 1 H).
2-[(1S)-1-\{((tert-butoxy)carbonyl)(methyl)amino\}-2-methylpropyl]-1,3-oxazole-4-carboxylic acid (SI-5b)

Ester SI-4b (1.90 g, 6.13 mmol) was added to a 250 mL flask with stir bar along with THF (60 mL) and water 5.6 mL). LiOH (306 mg, 12.3 mmol) was added and the flask was stirred for 24 h, after which time TLC analysis (10% MeOH/DCM) indicated that the reaction was complete. The reaction was diluted with DCM (~75 mL) and water (~50 mL), then the pH was adjusted to 4 with 2 M aq. HCl. The layers were separated and the aqueous phase was re-extracted with DCM (2 x 50 mL). The combined organics were then dried with sodium sulfate, filtered, and concentrated to yield the title compound as a pale yellow solid (1.76 g, 97%). The compound was advanced without further purification.

Tert-butyl N-[(1S)-1-[4-\{(1-hydroxy-2-methylpropan-2-yl)carbamoyl\}-1,3-oxazol-2-yl]-2-methylpropyl]carbamate (SI-6a)

Carboxylic acid SI-5a (2.25 g, 7.93 mmol) was dissolved in DCM (100 mL). HOBr (1.28 g, 9.50 mmol), DIPEA (4.82 mL, 27.7 mmol), and 2,2-dimethyl-2-amimoethanol hydrochloride (1.03 g, 7.92 mmol) were added, followed by EDC-HCl (1.82 g, 9.52 mmol). The reaction was stirred for 48 h, then the mixture was washed with water (75 mL), 0.1 M aqueous HCl (75 mL), and saturated aqueous sodium bicarbonate (75 mL). The organic phase was dried with sodium sulfate, filtered, and concentrated. The resulting crude oil was redissolved with DCM and purified by flash chromatography (100 g SiO\textsubscript{2} cartridge; 0 to 100% EtOAc/hexanes gradient) to yield a white solid (2.16 g, 77%), which was used in the subsequent step.
Tert-butyl N-[(1S)-1-{4-[(1-hydroxy-2-methylpropan-2-yl)carbamoyl]-1,3-oxazol-2-yl]-2-methylpropyl]-N-methylcarbamate (SI-6b)

Carboxylic acid SI-5b (1.71 g, 5.74 mmol) was dissolved in DCM (100 mL). HOBt (0.93 g, 6.91 mmol), DIPEA (3.50 mL, 20.1 mmol), and 2,2-dimethyl-2-aminoethanol hydrochloride (0.72 g, 5.74 mmol) were added, followed by EDC-HCl (1.32 g, 6.9 mmol). The reaction was stirred for 24 h, then the mixture was washed with water (75 mL), 0.1 M HCl (75 mL), and saturated sodium bicarbonate (75 mL). The organic phase was dried with sodium sulfate, filtered, and concentrated. The resulting crude oil was redissolved with DCM and purified by flash chromatography (100 g SiO$_2$ cartridge; 0 to 100% EtOAc/hexanes gradient) to yield a yellow oil (1.72 g, 82%), which was used in the subsequent step.

Tert-butyl N-[(1S)-1-{4-[(4,4-dimethyl-4,5-dihydro-1,3-oxazol-2-yl)-1,3-oxazol-2-yl]-2-methylpropyl]carbamate (SI-7a)

Amido alcohol SI-6a (1.90 g, 5.34 mmol) was added to a 250 mL flask with stir bar and sealed under nitrogen. DCM (60 mL) was added and the flask was cooled to -20 °C. Deoxo-Fluor (1.19 mL, 5.92 mmol) was added by syringe, and the reaction for stirred for 45 min. at -20 °C. The reaction was quenched by addition of saturated sodium bicarbonate (75 mL) and water (75 mL), then extracted with EtOAc (3 x 35 mL). The combined organics were dried with sodium sulfate, filtered, and concentrated. The resulting crude oil was redissolved with DCM and purified by flash chromatography (100 g SiO$_2$ cartridge; 0 to 100% EtOAc/hexanes gradient) to yield a white solid, m.p. 76–78 °C, (1.9 g, 87%).
