years arrive. The child bearing years are past. For most women it is a difficult time. Hormonal and other physiologic systems undergo major alteration. These changes exact from the emotional make-up of each woman equal measures of adjustment and alteration. The process of reproductive involution stirs anew the serious deliberations about a woman's role, responsibility and purpose in life. The anxieties of youthful menarche are revisited, but the mystery and challenge of fertility is not the problem. Instead there is apprehension and reluctance over the changes leading to infertility. For the woman who has tampered with these natural functions and aborted, there is so often an extra burden. For there arises from the realm of repressed conflicts the haunting reminder of the dreadful privlege of procreation is denied by old unsettled feelings. One sees one from the quiet murder. Yet it is felt. For in the mirror a trial is always held. The verdict: guilty and the sentence harsh. They are sentenced to bear a noise, constant and tormenting. It is an echo from the realm of repressed conflicts the haunting reminder of the dreadful privlege of procreation is denied by old unsettled feelings. One sees one from the quiet murder. Yet it is felt. For in the mirror a trial is always held. The verdict: guilty and the sentence harsh. They are sentenced to bear a noise, constant and tormenting. It is an echo from the quiet murder.

Dr. Curran practices general psychiatry in the Danvers-Salem, Mass. area. A graduate of Tufts Medical School, he interned at Salem Hospital where he is presently on the staff. His psychiatric residency was at Boston VA Hospital with clinical psychiatry training at Mass. General, serving on that staff also as well as Henn. Memorial Hospital in Danvers. He visited Danvers State Hospital as a member of the Mass. General teaching unit; he is also on the staff of the Rosary Clinic at Nazareth. Dr. Curran is also a psychiatric consultant at North Shore Catholic Charities.

Regulation of Ovulation Time In Normal Women With Clomiphene Citrate and Perfecting the Practice of the Rhythm Method

J. G. Boutrelis, M.D., N. Vorsys, M.D. and J. C. Ullery, M.D.

According to Marshall, the basic fundamentals of the rhythm method have been known to physicians for the past 35 years; however, this form of family planning has failed to obtain the confidence of a significant segment of the Catholic population. Even highly motivated and properly instructed patients frequently fail to accomplish their objective because of an unsuspected premature or late ovulation in an otherwise fairly predictable ovulatory pattern. These rhythm failures would imply that the responsible body processes which regulate the time of ovulation are not perfect and possess intrinsic peculiarities which prohibit repeated perfect timing of ovulation. Hypothalamic disturbance is but one example of how the pituitary-ovarian axis might disturb ovulation timing.

During the past decade, many steroid compounds have been made available for use in the area of family planning and their efficacy has been virtually 100 per cent. Their mode of action is attributed to a three-fold mechanism, namely: (1) Inhibition of ovulation, (2) production of a hostile cervical mucus, and (3) interfering with implantation of a fertilized egg by altering the endometrial environment.

It is not within the scope of this presentation to discuss the morality of their use.

The purpose of this report is to discuss our experience with clomiphene citrate and its ability to regulate the time of ovulation. Clomiphene is a new orally administered non-steroid compound which is an analogue of the weak estrogen TACE. Clomiphene was made available in 1960 for infertile anovulatory patients. When administered to these patients, ovulation occurred and is characterized by all scientific criteria of ovulation, including pregnancy. In a summarized report by Johnson et al, it was noted that 1809 out of 2616 anovulatory patients ovulated following the administration of clomiphene citrate and approximately 40 per cent became pregnant during the first three clomiphene treated cycles. The mechanism of action of clomiphene is by the direct stimulation of the ovary or by the stimulation of the hypothalamic pituitary axis.

In a careful review of the literature, there are no published reports concerning the use of clomiphene citrate in normal women for the regulation of ovulation time. The purpose of this study was to see if clomiphene citrate would regulate the time of ovulation and make the
practice of the rhythm method more effective.

MATERIAL AND METHODS

The 96 normal patients participating in this study were a group of highly motivated patients wishing to space or limit the number of children in their families by the use of the rhythm method. Their ages varied between 20 and 40 years of age with an average parity of four. Before admitted to the study, each patient presented documented evidence of six months of basal body temperature graphs. The administered dose of clomiphene citrate was 50 mgs. daily for 5 days beginning on the fifth day of the menstrual cycle. Basal body temperature graphs were maintained by each patient while on clomiph therapy. Patients were seen in the office each month for pelvic examination, cervical mucus study, B.B.T. graph review, vaginal cytology and, in selected cases, endometrial biopsy for histologic and histochemical analysis. This phase of the study was considered important to assure that no adverse changes occurred at or following ovulation which might interfere with the normal physiologic events leading to conception and implantation. One might conclude that these precautions were unnecessary, since previous documented studies dealing with 2616 anovulatory patients treated with clomiphene citrate responded favorably with ovulation and pregnancy.

RESULTS

Utilizing basal body temperature as an indicator of ovulation, comparisons were made of the patients' ovulatory patterns before and during clomiphene citrate therapy. Since the phrase "variation of ovulation" is repeatedly used throughout this study, an explanation of this phrase may be necessary. For instance, during the 6-month control period of B.B.T. recording, if a patient ovulated between day 14 and 16 of her cycles, then this patient had a variation of ovulation of three days. Therefore, the results of this phase of our study may be reported as follows:

1. During clomiphene therapy, ovulation was controlled within 3 days in 94 patients (97.9%) compared to 24 patients (25%) during the control period.

2. During clomiphene therapy ovulation time was controlled within 2 days in 89 patients (92.7%) compared to 18 patients (19%) during the control period.

3. In general, 95 out of 96 patients exhibited a significant improvement in their ovulatory pattern while on clomiphene therapy. With one exception, no premature or late ovulations occurred in patients under clomiphene therapy.

Viewing these results from a slightly different perspective, it was important to note when ovulation occurred following the last administered dose of clomiphene citrate. The overwhelming majority of ovulations (90%) occurred 6-8 days after the last dose of clomiphene citrate.

If the normal corpus lutein phase of the menstrual cycle is approximately 14 days, then clomiphene treated patients exhibited a corpus lutein phase of nearly 15 days. This is indirect evidence that clomiphene stimulates, rather than suppresses, pituitary gonadotropic secretions.

The menstrual cycle length under clomiph therapy exhibited excellent regularity with an overall increase in the cycle length of nearly 2 days. The character of the menses were normal in all but 5 patients. The latter reported heavier periods when compared to their pre-clomiph therapy menses.

Side reactions to clomiphene therapy included ovulatory pain (8), hot flashes (4), questionable hair loss (2), weight gain (1), itching (1), blurred vision (1), and moderate ovarian enlargement (3). All side reactions were considered mild and transient by the patients and investigators.

Studies on cervical mucus, vaginal cytology, and on endometrial biopsies were normal. Exhaustive laboratory studies have been documented by previous competent investigators in treating 2616 anovulatory patients with clomiphene citrate. These studies were designed to evaluate the pituitary, adrenals, thyroid, liver, blood and other body systems. No adverse functions to clomiph therapy were encountered.

CONCLUSIONS

Out of 96 normal patients participating in this preliminary study, all but one exhibited a beneficial effect in regulating menstrual cycle length and ovulation time.

The most common time for ovulation to occur is 6 to 8 days after the last administered dose of clomiphene. It should be emphasized that clomiphene does not induce a stereotype response of ovulation time in all patients. Though variations in ovulatory response exist between patients, each patient responds rather consistently during clomiph therapy. Therefore, each patient should be managed individually and not on a collective basis in determining their fertile and infertile periods.

The sequence of events concerned with fertilization and implantation are not affected adversely by clomiphene citrate therapy. This conclusion is based on the present observations and documented reports by previous investigators.

It should be emphasized that clomiphene citrate stimulates the processes concerned with ovulation rather than suppresses ovulation.

It is the authors' opinion that clomiphene citrate is a useful agent in regulating ovulation time and perfecting the practice of the rhythm method. More important than attempting to predict and pinpoint ovulation time is the ability of clomiphene citrate to prevent unexpected premature or late ovulations.

It is hoped that further studies with clomiphene citrate will suggest that patients practicing the rhythm method of family planning may discontinue the tedious task of B.B.T. recording while they remain on stabilized clomiph therapy.

**An Intellectual Spiritual Week-End**

**PHILIP C. ROND, M.D. AND EDWARD R. SCHUMACHER, M.D.**

In place of a yearly retreat, at the Diocesan Retreat House, the Guild of Catholic Physicians held an Intellectual Spiritual Week-End at one of the more quiet, modern motels in the Columbus, Ohio area. The resulting spiritual uplift was highly rewarding. An enthusiasm was generated that we have never seen in a retreat.

During the planning and discussion phase, in the winter months (it was held in April, 1966), there was a good exchange of ideas on pros and cons of substituting this type of week-end for the annual retreat. It seems in retrospect that it was the institutionalists versus the prophets. Father Murchland points out "there are two such inevitable dimensions to any religious or moral position."

Since institutional thinkers tend to conform to current patterns, these wanted an accepted routinized retreat. The prophetic minds were for reform and change. They wanted a new type of experience. They wanted to generate a Western religious cultural reform, rather than conform to the old norms. Again, we say, this was done without conscious awareness, without being aware, as Murchland points out, that the prophetic "argues for a serious revision of thought away from purely juridical modes of thinking, towards modes of thinking that better reveal the spiritual and ethical substance of our tradition. The prophetic is grounded in the priesthood of all the faithful and is historical. It is essentially dynamic and inventive."

The week-end as it finally developed was held at a modern motel, in a section that provided an attractive meeting room, and a high degree of privacy. It was attended by Catholic physicians and their wives. Non-Catholic physicians and other Catholic non-medical scientists were interested in participating, however, because it was the first venture in a new endeavor, they were not included. In the future it would seem advisable to expand the registration to include them.

The participants registered in Friday evening at 7 p.m., remained through Saturday, and checked out Sunday at noon. All meals were served on the premises. The only trip away from the meeting place was for Sunday Mass.

The week-end was a crowded one, with the emphasis on talking rather than silence. It was not just a matter of listening to the spiritual leader, in this case Father William McNamara of the Spiritual Life Institute, Sedona, Arizona, but rather a matter of listening to and exchanging ideas. Father McNamara shared the speakers table with three of the physicians who presented topics for discussion.

The conferences, seven in number, were held in a round table fashion. After each conference topic had been presented there followed group discussion which always had to be...
