Abstract

A general method has been developed for arylation of readily available 1H-perfluoroalkanes. The method employs aryl iodide and 1H-perfluoroalkane reagents, DMPU solvent, TMP$_2$Zn base, and a copper chloride/phenanthroline catalyst. Preliminary mechanistic studies are reported.
Many pharmaceuticals and agrochemicals contain aryl-trifluoromethyl or aryl-polyfluoroalkyl linkages. Consequently, introduction of fluoroalkyl substituents into aromatic systems has attracted intense interest. Trichloromethyl groups and other functionalities can be converted to trifluoromethyl moieties by treatment with a fluorinating reagent. A halide or, rarely, a hydrogen on an aromatic ring can be replaced with a trifluoromethyl group under transition metal catalysis. Examples of such reactions include palladium-catalyzed trifluoromethylation of aryl chlorides and ortho-trifluoromethylation of 2-phenylpyridines. More commonly, however, copper is employed for polyfluoroalkylation of aryl iodides. Typically, trifluoromethyltrialkylsilane reagents are used in combination with a stoichiometric copper source. A recent pioneering report describes reactions catalytic in copper. However, only electron-deficient aryl iodides react in high yields. Cross-coupling of aryl iodides and perfluoroalkyl iodides by employing 1–3 equiv copper metal has also been reported. Arene reactions with R₃F proceed by radical mechanisms and often result in isomer mixtures.

In most of the above cases, R₃SiR₃ reagents have been employed. However, only trifluoromethyl-, pentafluoroethyl-, and heptafluoropropyltrialkylsilanes are commercially available. Thus, a widely available perfluoroalkyl source should be sought to develop a generally useful synthetic methodology. We report here a method for copper-catalyzed 1H-perfluoroalkane arylation by aryl iodides.

Scheme 1. Reaction Development Considerations
Based on previous work on copper-catalyzed arylation of polyfluoroarenes, we considered the arylation of 1H-perfluoroalkanes (Scheme 1). The lowest homologues of 1H-perfluoroalkanes are among the cheapest sources of Rᵢ groups. Several issues had to be addressed to develop a viable method (Scheme 1). First, the stability of the perfluoroalkyl metal reagent generated in the deprotonation step needs to be considered. In contrast to pentafluoroaryl metals, most perfluoroalkyl metals are unstable. Only mercury, cadmium, bismuth, thallium, and zinc perfluoroalkyls are relatively stable. A viable methodology will not use highly toxic Cd, Hg, or Tl reagents; thus, Bi or Zn bases must be employed. Second, the base type needs to be determined. Trifluoromethane possesses a pKₐ of about 31 requiring an amide base for deprotonation. Bismuth amides are photolytically and thermally unstable. Consequently, a zinc amide base should be employed. The amide moiety should be hindered to prevent copper-catalyzed amination of aryl iodide. These considerations led to the selection of the zinc bis-2,2,6,6-tetramethylpiperidide (TMP₂Zn) base.

The reaction was optimized with respect to ligand and solvent (Scheme 2). For perfluoroalkylation of electron-rich 2-methoxyiodobenzene, a phenanthroline ligand additive afforded an increased conversion. However, high conversion to the product was observed for 2-iodopyridine perfluoroalkylation in both the presence and absence of phenanthroline. Presumably, the phenanthroline ligand stabilizes perfluoroalkyl copper species. Consequently, for functionalization of more reactive aryl iodides, phenanthroline may be omitted. Solvent optimization showed that the best results are obtained in DMPU which was used in all further reactions.

Scheme 2: Reaction Optimization

The perfluoroalkylation scope with respect to aryl iodides is presented in Table 1. We were pleased to discover that benzylated \( \alpha,\alpha,\omega \)-trihydroperfluoroheptanol was arylated by a number of aryl iodides under the optimized reaction conditions. Electron-rich 2-iodoanisole and 4-iodotoluene are reactive affording coupling products in moderate yields (entries 1 and 2). Reactions with electron-poor ArI are higher yielding (entries 3–5, 7, 11). Functional groups such as trifluoromethoxy (entry 3), nitrile (entry 4), bromide (entry 7), and ester (entry 11) are tolerated. Iodinated heterocycles such as 2-iodopyridine, 2-iodo-4,5-dimethylthiazole, and 8-iodocaffeine react to give products in good to excellent yields (entries 8–10). 2,6-Disubstituted electron-rich aryl iodides do not afford the coupling products. Instead, the iodide moiety is reduced. Unactivatedaryl
bromides are unreactive. Thus, reaction of 4-bromobiphenyl with benzylated α,α,ω-trihydroperfluoroheptanol under standard reaction conditions afforded the coupling product in <5% conversion.

The reaction scope with respect to 1H-perfluoroalkanes is presented in Table 2. The most difficult coupling partner is trifluoromethane (entry 1). Trifluoromethyl copper decomposes generating pentafluoroethylcopper unless it is stabilized by HMPA. About 10% of pentafluoroethylated substrate was observed in the crude reaction mixture, and purification by HPLC was required to obtain pure ethyl 2-(trifluoromethyl)benzoate. Reactions with other 1H-perfluoroalkanes, such as C₂F₅H, CF₃CF₂CF₂H, and 1H-perfluorohexane, are high-yielding (entries 2–5). Substrates possessing two –CF₂H moieties can be either monoarylated (entries 6 and 7) or diarylated (entry 8) depending on the reaction stoichiometry. Some functionality such as chloro and amide (entries 9 and 10) is tolerated. 2H-Heptafluoropropane is unreactive.

Preliminary mechanistic studies have been performed. The intermediate bis(perfluoroethyl)zinc species 1 was prepared by the reaction of TMP₂Zn with pentafluoroethane (Scheme 3). The complex was characterized by ¹H and ¹⁹F NMR, X-ray crystallography, and elemental analysis. Additionally, anionic copper complex 2 was prepared in low yield by reaction of CuCl, KF, and TMSCF₃ (Scheme 3). Complex 2 exists as a temperature and moisture sensitive colorless solid that slowly decomposes at RT under an argon atmosphere over the course of several hours, but is stable for at least 4 weeks at −35 °C under an inert atmosphere. It was characterized by ¹H and ¹⁹F NMR as well as X-ray crystallographic analysis.

**Scheme 3. Reaction Intermediate Synthesis**

Several ¹⁹F NMR experiments were carried out to determine the identity of the species present in the reaction mixture and their reactivity. Mixing CuCl and excess 1 in DMPU solvent affords negligible amounts of zinc to copper transmetalation products at 45 °C. However, the reaction at 90 °C affords several species that were tentatively identified by comparison with NMR of authentic 2 and reported spectral data for 3 (Scheme 4). Furthermore, a preformed mixture of 2 and 3 in the presence of excess 1 was subjected to the reaction with ethyl-2-iodobenzoate at 25, 40, 60, and 90 °C. At 25 and 40 °C, consumption of 2 and 3 is observed and 5 is formed; however, 1 does not undergo transmetalation with copper halide. Further heating at 60 °C is required for transmetalation to occur. Heating to 90 °C leads to the fast consumption of aryl iodide and 1 followed by the reappearance of 2 and 3. These experiments show that

transmetalation appears to be the turnover-limiting step for pentafluoroethylation of ethyl 2-iodobenzoate.

**Scheme 4.** NMR Experiments

The general reaction mechanism is presented in **Scheme 5**. Deprotonation of 1H-perfluoroalkanes with TMP2Zn affords bis(perfluoroalkyl)zinc species. Subsequent transmetalation with copper halide produces a mixture of anionic Cu species that reacts with aryl iodide, either directly or via a neutral perfluoroalkyl compound, \(^{5f}\) to give the coupling product.

**Scheme 5.** Reaction Mechanism

In conclusion, we have developed a general method for arylation of readily available 1H-perfluoroalkanes. The method employs aryl iodide and 1H-perfluoroalkane reagents, a DMPU solvent, a TMP2Zn base, and a copper chloride/phenanthroline catalyst.
